A deeper incision of the external sphincter ani is rendered necessary in certain cases of anorectal abscesses and fistulæ which arise in the anal canal, and for these the important principle of the two-stage operation with use of the silk ligature is recommended. Infection may begin in a crypt, abrasion, or an intramuscular gland, and usually extends out between the superficial and deep portions of the external sphincter. The most acute abscess of this type is the deep postrectal in which the infection extends back from the posterior part of the anal canal and then begins to spread laterally beneath the anococcygeal raphe into each ischio-rectal fossa. When an acute abscess of this sort is drained it is manifest that, on account of its depth, a considerable portion of the external sphincter will need division. On no account should the muscle be divided in the acute stage. If a probe-pointed director is passed through an internal opening high up posteriorly, a stout silk ligature (No. 8 or 12) is passed through the opening on a silver probe or aneurysm needle and is knotted loosely round the contained muscle. The ligature serves to mark the opening and to fix the sphincter muscle by causing it to adhere to the lateral margins of the wound. Two weeks later, under local anæsthesia, the sphincter is incised with scissors and the ligature cut out; sometimes on account of the height of the internal opening it is advisable to cut through the contained muscle in two successive stages. Complete drainage is thus effected and control is not impaired, for the sphincter becomes adherent to the margins of the wound before it is cut across, and later on, as healing progresses, the muscle-fibres become approximated as the scar contracts.

This principle of the two-stage operation is of the utmost importance and deserves wide recognition. It is suitable also for certain cases of anorectal fistulæ with an internal opening between the superficial and deep portions of the external sphincter. If the case is of the anterior horseshoe or semi-horseshoe type with a central track passing deep to a considerable portion of the external sphincter, a two-stage operation is usually imperative in view of the risk of causing incontinence by immediate division of the muscle; with a posterior track the risk is not so great, but even so no harm can ever be done by carrying out the operation in two stages. The time required for healing depends on the area of the wound made for drainage, and is not altered by whether the sphincter is divided at the first or a later operation. Caution is required, therefore, and if there is any doubt the operator can always be sure that the decision to carry out the operation in two stages is not likely to be wrong.

#### POST-OPERATIVE MANAGEMENT OF ANORECTAL WOUNDS

A satisfactory routine for the average rectal case is to have the bowels moved by an olive oil and gruel enema on the third morning after operation. The

importance of leaving the original gauze dressing until then has been mentioned; the gauze is removed by gentle traction on the third morning, assisted by irrigation with a dilute peroxide lotion from a douche can. This is done most easily when the patient is placed on his left side on the edge of his bed, with a mackintosh sheet underneath him leading into a bucket. In very nervous subjects Evipan anæsthesia may be used for this first dressing.

The average rectal patient is allowed to have a hot bath twice a day from the third day onwards, which together with the twice daily irrigation and dressing forms an important part of the after-treatment. The hot bath encourages drainage, and the warmth may help the granulation of wounds, and probably relieves sphincter spasm. In theory it might seem ideal to carry out less frequent dressings as in the Orr method, but in the case of the rectum the two important requirements for the wounds, immobilisation and asepsis, cannot be achieved. It would be difficult to keep the dressings reasonably clean, and there is no guarantee that a gauze dressing, put in after operation, will remain in perfect position from one day to another. The twice daily dressing with mechanical cleansing of the wound by a stream of warm lotion is comforting for the patient, provided that the dressing is done gently and capably. The organisation of rectal dressings on these lines is easy in a special hospital, but it can be done equally well with scattered rectal cases in a general hospital or a nursing-home. The nurses in charge of such cases soon learn to take the requisite trouble, which is rewarded by seeing the smooth progress of healing and by the patient's appreciation of diminishing pain with each dressing.

Two details are worthy of mention:

(1) The majority of cases with anal wounds which are healing by granulation, even if the sphincter has been well relaxed at the time of operation, will tend to develop a spasm or contraction of the sphincter unless steps are taken to counteract this. The passage of a finger every day would no doubt prevent this tendency, but it is difficult for a busy surgeon to do this with regularity, and a better and more uniform dilatation is achieved by the use of the St. Mark's Hospital dilator: the outer end of this dilator has a diameter of one inch. In cases of anal fissure this dilator is passed on the fourth post-operative day, lubricated with a zinc and castor oil cream, and it is passed subsequently by the surgeon, resident, sister, or nurse each morning and evening in the course of the dressings. In many cases of anal fistula the dilator is passed with advantage on the fifth or sixth day, and the same remark applies in the treatment after hæmorrhoidectomy.

I regard the regular use of this dilator as being a most valuable item in the after-treatment; its passage from an early date certainly saves the patient a great deal of pain and ensures smooth healing of the anal extremity of the wound.

(2) The method of inserting the actual gauze dressing is important. With the buttocks well retracted, a corner of folded gauze moistened or lubricated with whatever lotion or ointment may be selected, is tucked with sinus forceps into the anal canal, the external part of the gauze being arranged over the surface of the wound. This should be referred to as a flat dressing, and is not to be considered a plugging, which word gives a totally incorrect idea of the dressing.

There are many other points in connexion with anorectal wounds which I have not touched upon;

for instance, the importance of obtaining tissue for section in all cases of doubtful ætiology and also in inflammatory conditions in order to detect cases of tuberculous infection; the use of ultra-violet light to stimulate healing of wounds, and the occasional use of skin-grafting in certain abscess or fistula cases where an unusually large external wound has had to be made for drainage.

As a general rule, however, one of the objects in view is to delay the healing of wounds external to the anus in order to ensure proper healing of their inner extremities; it is this fact which renders the surgery of this part of the body rather tiresome, and it is well described by the old saying "slow but sure." The lessons of rectal surgery are, I think, worthy of attention, and a man who learns how to open a large ischiorectal abscess and bring the case to a successful conclusion is probably well equipped to deal efficiently with an acute abscess in any other part or tissue of the body. It is instructive to observe that a wound can heal by granulation and yet leave a linear scar, which after the lapse of some months becomes almost indistinguishable from one that has healed by primary union.

### THE INITIAL STATE PRINCIPLE AND ITS IMPORTANCE IN PHYSIOLOGY AND PATHOLOGY

BY S. LEITES, M.D.

PROFESSOR OF PATHOLOGICAL PHYSIOLOGY IN THE INSTITUTE FOR  
POSTGRADUATE MEDICAL INSTRUCTION AND THE INSTITUTE  
OF EXPERIMENTAL MEDICINE, KHARKOFF, U.S.S.R.

UNTIL recently the reaction of an organism to a given stimulus was considered to depend on the intensity of the stimulus and its specific nature. It is, however, obvious that the state of the reacting object and of its environment must also play their parts in determining the quantity and quality of the reaction. These indeed are sometimes even more important than that played by the stimulus itself.

Rössle has demonstrated a condition which he has called "pathergy" in which the application of a stimulus leaves the organism in a state in which it is unduly susceptible to subsequent stimuli of a different kind: for example, in some cases of Graves's (Basedow's) disease, tachycardia persists even after the secretion of the thyroid gland has become normal; and a rabbit which is given intravenously a non-lethal dose of cholera vibrio will die if, on the next day, it is given an injection of ordinarily harmless saprophytes. This led Moro and Keller to the conception of a state of "parallergy" in which an allergic state, produced by specific sensitisation, predisposes the body to react to non-specific stimuli. This form of pathergy is seen in the child who develops a positive tuberculin reaction after small-pox vaccination, and Rössle suggests that encephalitis, arteritis, nephritis, and other complications of contagious diseases may be explained in the same way.

Obviously the pathergic state is a much more important factor in the response to a stimulus than is the stimulus itself. True the pathergy was originally due to a stimulus, but once established it alters the reaction to subsequent stimuli, which, in their turn, condition its future development.

How are we to judge, in any particular case, which is of chief importance—stimulus or receptor? Experimentally we may find that a given stimulus always produces the same reaction and that the latter changes

when the stimulus is varied. In these circumstances it is the stimulus that is "dominant." Alternatively we may find differing responses to equal stimuli, and here the chief part must be played by the reacting object. When the character of the stimulus is the most important factor in the interaction of stimulus and object the character of the reaction is determined by its intensity or "dose." But when the reacting substratum of the object is more important, search must be made for another indicator which will be a function of the object. A helpful suggestion as to where we are to look for such an indicator is provided by Wilder's "law of initial value" (Ausgangswertgesetz).

#### THE LAW OF INITIAL VALUE

Wilder showed that the responses of the pulse and blood pressure of a given person to a given dose of adrenaline and atropine vary inversely with the pulse-rate and blood pressure at the time of the injection. The quicker the pulse and the higher the blood pressure to start with, the less they are affected by the introduction of a fixed dose of the drugs. When the initial value of the blood pressure is high enough, the response may even be negative instead of positive—i.e., adrenaline produces a vagotonic rather than sympathicotonic response. From this Wilder deduced a regular interdependence between the initial value of the blood pressure (or pulse-rate) and the character of their reaction to stimuli. Developing this idea, he points out that since the initial value may depend on the state of both divisions of the vegetative nervous system, the effect will depend on how far one of these is already excited. If there is already great hypertony the influence of a stimulant drug is reduced and may become paradoxical and sedative. Thus in bradycardia due to vagus overaction we may find a weak, or even negative, response to pilocarpine and an increased response to adrenaline and atropine. As Wilder puts it, the more intense the function of a vegetative organ, the weaker is its capacity for being excited by stimuli and the stronger its reaction to depressing factors. Smirnoff's concept of the "functional tendency," a factor which determines the reactivity of the vegetative nervous system to endogenous and exogenous stimuli, is in perfect harmony with Wilder's principle. Strong reflexes, he finds, indicate depressed tone in the centres under investigation.

This law of initial value has been demonstrated in operation in many different circumstances, by Wilder and also in our own investigations. For example it has been shown that the effect of adrenaline is greater after removal of the suprarenals—probably because of the low initial value of the blood pressure. On the other hand, old people with high blood pressure react poorly to the same drug. Both adrenaline and ergotoxine cause tonic contraction of the isolated uterus; but if they are applied one after the other (the perfusion fluid being renewed so that the two do not act together) the second either will not exert its specific influence or will produce the paradoxical effect of Langecker. A second injection of pituitary extract given a certain time after the first unit produces a less effect, because the initial value is raised by the first injection. The diuretic effect of pituitrin also varies: in diabetes insipidus it reduces the flow of urine whereas in reflex anuria it increases it. Similarly, parathormone raises the blood calcium in tetany, when the initial value is low, and depresses a level artificially raised by the intravenous injection of calcium. Thyroxine raises the basal metabolism in myxœdema but not in Graves's disease, where

it may even lower it; and it is worth noting that iodine used in Graves's disease will usually prove helpful for eight days or so, until the metabolic rate has reached a certain level, after which it begins to act in an opposite sense.

FIG. 1.—Effect of doses of linseed oil on the bile secretion of dogs. The response (shown by the stippled areas) is greater if secretion during the previous 12 hours (shaded areas) has been small.

seen that this is greatest if the flow during the previous 12 hours has been comparatively small. The same effect is obtained using other stimuli—e.g., peptone (Fig. 2). Failure to allow for variations in the initial state of the bile secretion is probably one of the causes of the contradiction in published data concerning the effect of alimentary stimuli upon this function. Changes in the chemical composition of the bile—e.g., cholesterin content—after taking food may also depend on its initial composition. Thus we

FIG. 2.—Effect of peptone on bile secretion of dogs, showing maximal response when previous secretion has been lowest.

large number of diseases. Thus ingestion of oil in cases of hepatic disorder causes hypocholesterinæmia whereas in normal persons, or during convalescence, it leads to an excess of cholesterin in the blood (Leites and Golbitz-Katschan). When studying the pathology of fat metabolism in diabetes we (Leites, Sorkin, and Agaletzkaia) established in some cases that the behaviour of the neutral fat, and of the ketone bodies, was related to their initial value (Table I). It will be seen that, in the case illustrated, when the initial value of the fat and ketones was normal a

dose of fat (75 g. of butter) increased the neutral fat and decreased the ketones; but with the same patient on an Adlersberg-Porges diet (containing the minimum of fats) the same dose lowered the fat content and raised the ketones of the blood, since the initial value of the fat was high and that of the ketones was low.

The observations I have cited make it clear, I hope, that the law of initial value has general applica-

TABLE I

Effect of a dose of 75 g. of butter on the neutral fat and ketone bodies of a patient on an ordinary diet (A) and of the same patient on a diet poor in fats (B).

Patient.	Neutral fat mg. per 100 c.cm.			Ketone bodies mg. per 100 c.cm.		
	Before.	3 hrs. after.	6 hrs. after.	Before.	3 hrs. after.	6 hrs. after.

B	171	163	104	6	12	12

tions to physiology and pathology, and that it does something to explain the reaction of an object to a given stimulus, to which I referred at the beginning of this paper. Nevertheless it cannot be applied without reservations. The bare numeral of the initial value does not always adequately represent its quantitative character, and before we proceed to argue from the "initial value" we must ascertain how far it really corresponds, in the given case, to the initial state; for in one and the same initial states there can be different initial values and vice versa. That is why I consider it preferable to speak not of the "law of initial value" but of the "principle of the initial state," endeavouring to discover in every case the relation of this state to the indicator of the initial value.

THE INITIAL STATE

Such an indicator can be of assistance only if we are sure that the stimulus is acting purely on the object whose state it indicates. Now in diabetes as well as in myxœdema we may observe a high level of neutral fat in the blood. In diabetes, following the law of initial value, this level is reduced by ingestion of fat; yet in myxœdema it is increased (Leites, Sorkin, and Agaletzkaia). The reason of this is that in diabetes the high fat content of the blood is due to fat being transported from its depôts to the liver (because of diminution of hepatic glycogen) whereas in myxœdema it is due to disturbances in fat breakdown. In diabetes ingestion of fat fills the liver, reduces its transport from the depôts, and so lowers the fat content of the blood stream; but in myxœdema there is no reason why it should do so since it in no way affects the processes of fat combustion. Thus in diabetes we have an example of a stimulus acting on the object whose state is indicated

FIG. 3.—Effect of peptone on the cholesterin content of bile, showing a decrease when this was previously high. There is little change when it was previously low.

by the initial value; whereas in myxœdema we have not.

There is also another particular in which Wilder's law of initial value requires modification. According to him the paradoxical reaction is to be expected only if the functional activity of the reacting organ is high. Our experience, and published records, show, however, that such a reaction may be obtained also when its activity is much depressed. The excitability of a vegetative organ may be greatly lessened, and even inverted, by exhaustion of its energies by previous activity or by disease.

Analysis of the conditions under which the principle of the initial state does and does not apply makes it possible to recognise the conditions underlying the responses. The exceptions to the rule may be due first to variation in the reactions and secondly to compensatory processes. The presence or absence of compensatory processes determines, in fact, whether the principle of the initial state shall or shall not manifest itself. This statement is amply borne out by work on the physiopathology of the fat and lipid metabolism in various endocrine disorders.

A typical example is shown in the case of a patient who was admitted suffering from uncompensated diabetes. The blood-sugar was 208 mg. per 100 c.cm., and there were large quantities of sugar and acetone in the urine. A meal containing 75 g. of butter gave the results shown in Table II.

TABLE II

*Effect of a meal of 75 g. of butter on the metabolism of a diabetic before and after compensation*

	Neutral fat mg. per 100 c.cm.				Ketone bodies mg. per 100 c.cm.				Sugar in urine.	Acetone in urine.
	Before meal.	3 hrs. after.	6 hrs. after.	9 hrs. after.	Before meal.	3 hrs. after.	6 hrs. after.	9 hrs. after.		
March 10th.	130	102	114	208	65	83	82	80	3.4%	++
April 14th.	243	147	133	120	21	18	24	20	0	0

Although the initial values of the neutral fat and ketone bodies were relatively high they rose nine hours after the meal. Whereas it may be that in other cases, in which the diabetes was compensated, a decline in the ketone bodies was produced by the fatty meal. This patient was suitably treated by diet and insulin, and his diabetes was eventually compensated—i.e., the fasting blood-sugar level became lower and the acetone and sugar disappeared from the urine. His reaction to a butter meal was now, although the initial level of the neutral fat was still considerable, higher than it had been before: 243 mg. After the meal it sank rapidly and by the ninth hour it had reached 120 mg.; the ketone bodies did not rise. This was a paradoxical reaction.

The effect of a glucose meal provides another example of the working of the law. When the blood-sugar is artificially raised by the administration of glucose, and a glucose meal is then given, the blood-sugar will not be increased further, because the islets of Langerhans have been stimulated by the earlier administration of glucose (effect of Staub-Traugott). In diabetes, however, although the initial value of the blood-sugar is high, the islets do not compensate, and therefore a glucose meal will raise the blood-sugar.

## CONCLUSION

It is possible, therefore, to formulate the principle of the initial state as follows. If the reactive capacity of the vegetative system is altered in such a way that

it reacts weakly to a stimulant and strongly to a depressant, the state of the system must be the paramount factor in determining the reaction to stimulus. It is possible to deduce from this alteration the character of the initial state of the system—i.e., whether its excitability is high or low—and also to form an estimate of the extent to which the system is compensated and the possibility of accommodation.

The practical importance of the principle is therefore considerable. It allows a definite interpretation to be given to many series of phenomena, and in particular to the phasic action of certain stimuli. The alternation of phase in the action of hormones, drugs, nutritive stimuli, and many other agents may be due to the fact that the first stage of their action changes the initial state of the vegetative system, so that the second stage of the action produces an opposite reaction. But the second phase itself brings about another change in the initial state, so that the next reaction is more analogous to the first. For instance, a glucose meal will produce hyperglycæmia but will also change the initial state of the islets, so that hypoglycæmia is gradually induced. This condition, however, stimulates the suprarenal glands and, by changing their initial state, brings about a fresh hyperglycæmic state. The similar alternation of states of hyper- and hypo-lipæmia and ketonæmia after a fatty meal is probably due to the alteration in the initial states of the liver, the pituitary gland, and the thyroid which each of the phases provokes.

Recognition of the principle must modify many current views of pathology. A patient with bradycardia may sometimes be "vagotonic" in the sense indicated by Eppinger and Hess—that is, he must have a weak or even a paradoxical action to adrenaline. According to the initial state principle, however, it is quite possible that a patient with bradycardia who reacts strongly to adrenaline may none the less be "vagotonic" too. In fact, the strong reaction to adrenaline actually indicates a high degree of vagal excitation. Kylin, observing that in essential hypertonia the adrenaline action is weakened and "vagotonic," regards this disease as a "vagotonic" syndrome. But if the principle of the initial state is applied, the essential hypertonia may be regarded as indicating a high degree of sympathetic excitation, which, of course, reduces sensitiveness to adrenaline.

The principle of the initial state should give valuable assistance in various fields of medicine, and in suitable cases assist the correct assessment of the processes at work.

WEST LONDON HOSPITAL.—Presiding over the annual meeting of this institution on May 21st, Prince Arthur of Connaught said that the Silver Jubilee extensions were now practically complete. The extensions include new casualty, X ray, and pathological departments. All but £4000 of the necessary money has been received.

## THE PROBLEM OF REPAIR AND REGENERATION OF THE SEMILUNAR CARTILAGES

BY A. G. TIMBRELL FISHER, M.C., M.B., Ch.B. Brist.,  
F.R.C.S. Eng.

HON. ORTHOPÆDIC SURGEON TO THE ST. JOHN CLINIC AND  
INSTITUTE OF PHYSICAL MEDICINE, LONDON, ETC.;  
FORMERLY HUNTERIAN PROFESSOR OF THE ROYAL  
COLLEGE OF SURGEONS OF ENGLAND

SOME years ago I carried out an experimental investigation into the repair of fractures of the semilunar cartilages of the knee-joint. By injection methods it was found that the peripheral portions of the menisci were well supplied with blood-vessels partly derived from the delicate layer of synovial membrane which extends for a short distance over the extreme peripheral part of the cartilage. No vessels could, however, be traced in the inner or concave portions of the semilunar cartilages, and it appears on clinical and experimental grounds that the central portions of the semilunar cartilages are poorly nourished. Experiments on animals showed that incisions in the more central parts of the semilunar cartilages remained unhealed indefinitely but that incisions in the peripheral area were repaired by fibrous tissue after a considerable lapse of time. This experimental work has since been confirmed by various workers.

### REPAIR

The nutrition of the semilunar cartilages is of considerable clinical significance. It is probable that many minor injuries of the semilunar cartilages, particularly small longitudinal tears involving the convex edge, may heal by fibrous tissue, and sometimes evidence of such healing can be seen in cartilages that subsequently have to be removed owing to some further injury. Such cases may remain free from symptoms after manipulation (if locking exists) and appropriate after-treatment. Experience teaches, however, that most lesions of the semilunar cartilages are much more serious, and that in the great majority manipulative replacement combined with special after-treatment is merely of temporary benefit. The long period of complete rest formerly advocated after manipulative replacement of the torn and misplaced cartilage appears for physiological reasons to be useless in materially bringing about repair of the fractured cartilage, and the enforced rest may have troublesome sequelæ in the form of adhesions and muscular wasting. Taking into regard these facts and also the satisfactory results of operation in experienced hands, the question arises: Is it worth while to adopt conservative measures when the lesion is clearly of a severe nature? The answer appears to be that no hard-and-fast rule is possible, and that each case has to be considered from many different aspects before a decision is made.

In persons whose livelihood is at stake, as in many professional footballers, I believe that early removal of the torn cartilage is the wisest policy. Occasionally the player carries on quite well for a variable period after conservative treatment, but recurrence is, in my experience, almost certain; moreover, the playing of such a strenuous game while a torn cartilage is still present in the knee is apt to lead to osteoarthritic changes.

### REGENERATION

So far the healing of injuries of the semilunar cartilages and the clinical implications have been briefly considered. The equally interesting and important problem of regeneration of the semilunar cartilage after removal will now be discussed. One is often asked by patients if anything takes the place of the semilunar cartilage after removal, and why the knee is not permanently weakened by the operation. This is a problem of absorbing interest and concerning which our knowledge is at present immature. It must have fallen to the lot of many orthopædic surgeons to reoperate upon knees for recurrence of symptoms after a previous operation "elsewhere." This experience has befallen me several times. It is often very difficult to ascertain the state of affairs at the original operation, but at the second operation I have often found a structure resembling the semilunar cartilage and presenting various types of lesion, and I have hitherto assumed that in such cases incomplete removal had previously been practised. Some surgeons, for example, remove only the detached central portion of a bucket-handle lesion leaving the peripheral portion in situ. At a second operation by another surgeon for some other condition such as loose body, this peripheral portion might easily, in the absence of adequate details concerning the first operation, be considered a case of regeneration of a semilunar cartilage.

In the second edition of my monograph on internal derangements of the knee-joint (1933) I expressed the opinion that no case could be made out for regeneration of the semilunar unless an experienced surgeon, having carefully removed the cartilage, finds at a second operation that a structure resembling the semilunar has been reconstituted. A short time after making this statement two cases of apparent regeneration of a semilunar cartilage came under my personal observation.

### CASE RECORDS

CASE 1.—A professional football player was brought to me in November, 1929, and gave the following history. Three years previously an operation was performed upon the right knee for "removal of internal semilunar cartilage." In October, 1929, while playing football, he received a severe blow on the outer side of the right thigh while the right foot was planted firmly on the ground; the thigh was apparently rotated violently inwards upon the fixed leg. There was severe pain, a fairly convincing history of mechanical locking, and, subsequently, a large synovial effusion. Pain and weakness of the knee had persisted in spite of physical treatment.

On examination, synovial effusion of moderate degree was present and tenderness over the external semilunar cartilage. Flexion was painful, restricted, and associated with the click or snap so often present with a semilunar cartilage lesion. Operation was performed by me one week later and a complete bucket-handle lesion of the external semilunar cartilage was found. The whole of the torn cartilage was very carefully removed with the exception of the extreme posterior portion. Progress was uneventful and the knee functioned perfectly for three seasons.

On Nov. 18th, 1933, while playing football, his right knee was injured in a very similar manner to the previous occasion. Mechanical locking again occurred. X ray examination revealed some degree of lipping of the outer margin of the tibial condyle, and two loose bodies, one in front of the tibial spine and another at the back and outer side. It was considered that the symptoms were due to the loose bodies and operation was performed on Dec. 19th, 1933. The joint was opened through a curved incision over the antero-external aspect and a dense fibrous structure exactly similar in naked-eye appearances to the external semilunar cartilage and presenting a

longitudinal (bucket-handle) fracture was noted. It is of considerable interest to note that at the first operation, three years before, a similar type of lesion of the external semilunar cartilage was found to be present. The major portion of the regenerated and refractured cartilage and also the loose bodies were removed. No microscopical examination was made in this case.

CASE 2.—A professional football player severely twisted his left knee on Christmas Day, 1928. Severe pain was experienced on both inner and outer aspects of the joint but apparently there was no mechanical locking; a large synovial effusion ensued. He abstained from playing for ten weeks but every attempt to resume was accompanied by pain on both inner and outer aspects of the joint, and by synovial effusion.

On examination, May 13th, 1929, there was slight effusion in the left knee and slight limitation of full flexion of the left knee associated with pain. There was a well-marked click or snap on the outer side of the joint on flexion and also tenderness over the external semilunar cartilage and wasting of the quadriceps extensor cruris. The X ray showed an osteophyte growing from the inner surface of the internal tibial condyle. The case was clearly of a complex nature and it was considered that the symptoms referred to the inner side of the joint were probably due to interference with the action of the tendons of the sartorius gracilis and semitendinosus from the presence of the osteophyte, and that the symptoms referred to the outer side were due to a lesion of the external semilunar cartilage.

Operation upon the left knee was performed on June 25th, 1929. The osteophyte on the inner side was first removed by the chisel through a small internal incision. A separate incision was next made on the outer side of the joint and the condition of the external semilunar cartilage investigated. An oblique fracture at the junction of the middle and posterior thirds was discovered and the cartilage completely removed. Blood-stained synovial effusion was present and a few melon-seed bodies. The joint was closed after irrigation with normal saline solution.

Subsequent progress was uneventful and he resumed playing in the autumn and continued normally until March, 1934, when during a game he received a fresh injury to the left knee, which was severely rotated. A painful mechanical block to complete extension supervened immediately, followed by synovial effusion of moderate degree. On examination a few days later, synovial effusion was marked. There was a slight mechanical restriction to complete extension and localised tenderness over the middle of the external lateral ligament where also some structure (? cartilaginous) could be palpated and rolled under the examining finger. X rays showed a faint shadow which it was thought might be a loose body in the postero-external compartment of the joint.

A second operation was performed on March 24th, 1934. I used my semilunar skin flap on the outer side of the joint, which was opened by capsular incisions anterior and posterior to external lateral ligament. It was at once apparent that the symptoms were caused by a lesion of a regenerated external semilunar cartilage. This lesion was of the bucket-handle type but affecting the posterior part of the semilunar. The "handle" lay wedged between the external condyles of the tibia and femur where from its position it caused a mechanical block to complete extension and calcification had occurred in this portion, accounting thus for the shadow seen on X ray examination. The movable body felt beneath the external lateral ligament was the outer or peripheral portion of the bucket-handle. Only the anterior part of this is shown in the Figure; it had the normal attachments

CASE 2.—Regenerated external semilunar cartilage. Above = anterior; below = posterior.

wedged between the external condyles of the tibia and femur where from its position it caused a mechanical block to complete extension and calcification had occurred in this portion, accounting thus for the shadow seen on X ray examination. The movable body felt beneath the external lateral ligament was the outer or peripheral portion of the bucket-handle. Only the anterior part of this is shown in the Figure; it had the normal attachments

but was about half the width of the normal cartilage and its inner portion was thin and semitransparent.

Just as one swallow does not make a summer, so is it impossible to establish a fact of considerable importance by experience gained from two clinical cases. This short paper is contributed with the hope that it may stimulate discussion among other surgeons who have special experience in knee operations.

Dr. L. W. Proger, the pathological curator of the Royal College of Surgeons, has kindly examined microscopic sections of the regenerated semilunar cartilage, but excluding the area of calcification, and reports that these show nothing but dense fibrous tissue.

## HISTIDINE IN THE TREATMENT OF GASTRIC AND DUODENAL ULCER

By R. H. GARDINER, M.B. Oxon.

LATE HOUSE SURGEON AT THE GRIMSBY AND DISTRICT HOSPITAL

DURING the months August–December, 1935, twelve consecutive cases of gastric and duodenal ulcer admitted to the Grimsby and District Hospital were submitted to a new routine treatment in order to test the value of histidine as a curative agent.

#### TREATMENT

On admission, if radiography with barium meal, and if a fractional test-meal, in conjunction with the gastric history and symptoms, pointed to the presence of an ulcer, the histidine treatment was carried out as follows:—

A light solid diet with meals at the usual time was given. Patients were encouraged to take exercise on the ward balcony daily, and they were not confined to bed, being allowed up in the ward. Smoking in moderation was not prohibited.

Daily intramuscular injections of 5 c.cm. of Larostidin were given into the buttocks, 25 injections being given in all. Small doses of alkalis were prescribed at the beginning of the course when there was pain after meals, but were rarely necessary after the tenth day. At the end of the course control radiograms and fractional test-

HISTORY, DIAGNOSIS, AND RESULTS OF HISTIDINE TREATMENT

No.	Age.	Date of admission: symptoms.	Findings.	Condition at end of treatment.	Condition on April 1st, 1936.
1	40	August 12th, 1935: Pain 2 hrs. after food, severe at night; anæmia.	Duodenal ulcer.	Cured.	No pain; very fit indeed.
2	32	Nov. 25th: Persistent "gastric" trouble for years, with treatment; very little freedom.	Gastric ulcer; very high gastric acidity.	Complete relief.	1 mth.'s freedom, but pain has returned.
3	43	August 12th: Very severe epigastric pain for 10 wks., typical of gastric ulcer.	Large gastric ulcer on lesser curvature.	No symptoms except for occasional water-brash. Ulcer still found in radiograms.	Very fit; eats anything. No indigestion or pain.
4	69	Oct. 17th: Years of gastric trouble with loss of weight, and pain 2½ hrs. after food.	Duodenal ulcer.	Much better.	Pain returned 1 wk. ago but not so severe as before.
5	32	August 8th: "Acute indigestion" 6 mths., with pain 2 hrs. after food.	Pyloric ulcer; high gastric acidity with climbing curve in test-meal.	Cured, but high resting acidity remained.	..
6	27	Dec. 16th: Severe pain 20 mins. after food, with acid eructations. Anæmic.	Gastric ulcer.	Symptoms cured.	No further trouble.
7	45	Oct. 15th: Pain 4 hrs. after food. Melaena.	Duodenal ulcer.	Symptoms cured.	..
8	43	Dec. 16th: Persistent pain after food; sudden onset and melaena.	"Hour-glass" stomach; high acidity with climbing curve. Pyloric ulcer.	Better.	..
9	38	Nov. 25th: 8 yrs., symptoms of duodenal ulcer.	Duodenal ulcer with high acidity.	Cured.	Gained 1st. in weight. No further trouble.
10	50	Sept. 30th: Years of epigastric pain, always ½ hr. after food; two hæmatemeses.	Pyloric ulcer; high climbing curve, gastric acidity.	Better.	Pain now as bad as ever.
11	49	Sept. 2nd: Pain ¼ hr. after food, with persistent nausea.	Gastric ulcer.	Symptoms cured; ulcer not seen in radiograms.	Very fit indeed.
12	68	Nov. 12th: Admitted as emergency with hæmatemesis; long history of gastric trouble.	Gastric ulcer; hæmatemesis treated on usual lines, followed by larostidin; very high gastric acidity.	Symptoms cured; gain in weight.	No further trouble.

meals were repeated. All the patients treated were men of the labouring class. The whole course averaged a month. The series of 12 cases are recorded in the Table, with a brief history, the diagnosis, and the results obtained; the Figure shows the typical fall in gastric acidity.

Effect of histidine on gastric acidity.

RESULTS

Symptomatic relief was obtained in all cases, and there was an invariable fall in gastric acidity. Of 9 cases followed up 6 were fit and well after 4-6 months, whilst in 3 there had been a return of symptoms.

ADVANTAGES

Compared with the ordinary medical treatment for ulcers—namely, four weeks in bed on a graduated diet—the new treatment has the following advantages. It is far more congenial to the patient whose only inconvenience is the daily injection. There is no irksome diet of ten days of citrated milk and a graduated diet with prolonged confinement in bed. The treatment is also far simpler, with less trouble to the nursing staff, and the time taken is slightly less than the diet treatment.

CONCLUSIONS

Results obtained in the series show at least a temporary loss of symptoms comparable with those

obtained by ordinary medical treatment. It is doubtful if histidine has any healing effect on the ulcer directly, its action probably being a reduction in gastric acidity and a lowering of gastric motility. The ulcer has therefore a chance to heal, as the irritative factors are removed with a consequent loss of symptoms. Although not actually confined to bed the patients were not performing the heavy work to which they were accustomed and this also no doubt aided recovery.

There are distinct possibilities for this form of treatment, particularly among sedentary workers. An ambulatory treatment of ulcer could be carried out while they perform their usual daily routine, thus avoiding in many cases the loss of time of an enforced rest of over a month. The course of injections can be repeated if there should be an exacerbation.

Compared with the dietetic method, the cost of treating ulcers on the above lines was found to be about the same or a little less, since the average time taken in hospital was shorter, which helped to balance the cost of the larostidin. To the patient, however, it was a saving, for a normal life could be entered upon as soon as the course was finished, without the necessity of a convalescence period.

It does not seem possible that a lasting cure is to be obtained from histidine as from any other form of medical treatment for chronic ulcer similar to those in the cases recorded, but it is a form of treatment which I found gave satisfaction to both patient and physician.

I wish to record my thanks to Dr. J. W. Brown, honorary physician to the Grimsby and District Hospital, for permission to publish these cases admitted under his care.

## WEIGHT OF THYROID GLAND AND ATHERO-SCLEROSIS

BY NIELS P. DUNGAL, M.D.

PROFESSOR OF PATHOLOGY, UNIVERSITY OF REYKJAVIK, ICELAND

WORKING as pathologist in Iceland I have been struck by two things which apparently were different from what I had seen on the continent (in Austria and Denmark): (1) the small size of the thyroid gland; and (2) the rarity of athero-sclerosis. During the past year I have weighed most of our thyroid glands in order to obtain knowledge of its average weight in healthy Icelandic persons.

According to Thomas<sup>1</sup> the thyroid gland weighs 3 g. at birth, decreases during the first year of life to weigh 2 g. after twelve months, but has regained its initial weight of 3 g. at 3 years. From this age it increases in weight by 1 g. per year until 25 years, and in the following 10 years by 3 g. Wegelin<sup>2</sup> finds the weight of the thyroid almost constant from 20-50 years, Jaffé<sup>3</sup> also. In order to determine the normal weight for grown-up people in Iceland I have taken the average weight of thyroid glands in this age-period. Our findings are as follows:—

	Average weight of thyroid gland in grammes.
20 females, aged 20-50 years .. ..	11.3
14 males, " " " " " " " " " " .. ..	14.9
57 males and females above 20 years of age .. ..	13.3

The numbers are not great, but they reflect no doubt correctly the state of affairs in Iceland. Among 14 males the smallest gland weighed 7 g., the biggest 24, one 12, and one 13, but all the others 14-16 g. In the women the smallest gland at this age-period was 7 g., the biggest 19 g.; of 20 glands six were below 10 g. In the 61 bodies above 20 years from whom the glands were weighed we found four above 40 g., all in females. Two had Graves's disease (54 and 57 years), the two others were 47 and 67 years of age. These glands were evidently abnormal and not included in the above survey. In three we found glands weighing 21-27 g., one female and two males, one of them a foreigner. In all the other 54 who were 20-70 years of age the thyroid gland was below 20 g.

### COMPARISON WITH OTHER COUNTRIES

It is interesting to compare our figures with those of other countries:—

	Average weight of thyroid gland in grammes.
Germany (Vierordt <sup>4</sup> ) .. ..	33.8
(Orth, <sup>5</sup> Berlin) .. ..	30-60
(Weibgen, <sup>6</sup> Bavaria) .. ..	37.2
(Hück, <sup>7</sup> Kiel and Rostock) .. ..	20-25
Italy (Castaldi, <sup>8</sup> Florence) .. ..	20-25
Switzerland (Rössle, <sup>9</sup> Berne) .. ..	37-55
( " " Basle) .. ..	25-30
Belgium (Thomas, <sup>1</sup> Ghent) .. ..	20-27
France (Guiart, <sup>10</sup> Letulle <sup>11</sup> ) .. ..	24-25
U.S.A. (Jaffé, <sup>3</sup> Chicago) Whites .. ..	28
♂	♀
England* .. .. 20.5 g.	19.4 g.
Japan (Horisawa <sup>12</sup> ) .. .. 17.5 g.	15.3 g.
Iceland .. .. 14.9 g.	11.3 g.
	12.8

Wegelin attributes the smallness of the thyroids in Japanese to their relatively small body-weight, but

\* I am greatly indebted to Prof. Turnbull, London Hospital, for permission to publish figures collected from his post-mortem protocols, where the weights of different organs are carefully recorded. These figures are from the 1934 protocol, being the average weights of 52 females and 78 males between 20 and 50 years (4 cases of Graves's disease and 13 glands above 40 g. in this age-period being omitted).

this argument is not valid for Icelanders, who are, according to Hannesson's<sup>25</sup> measurements, among the tallest people of Europe.

The question arises which of the above-mentioned figures are to be regarded as "normal" for the thyroid gland. It is evident that Vierordt,<sup>4</sup> in his "Daten und Tabellen," has adopted too high a standard, and most authors now agree that 20-25 g. should be regarded as the average normal weight for grown-up persons. Then the figures from Japan and Iceland would be too low and one might expect symptoms of dysthyreosis among these nations. As to Iceland, signs of this are unknown, and basal metabolism is on much the same level as in other countries. The fact that we have two cases of Graves's disease among 286 autopsies might point to a tendency to hyperthyroidism, but our figures are too small yet to permit a judgment on that point.

### FACTORS INFLUENCING SIZE OF THYROID

We know that the goitre districts in Europe, North America, Asia, and Africa are practically all in the inner parts of the continents (in England, Derbyshire). Although the problem of aetiology is still a matter of controversy, the theory of iodine deficiency, advanced by Chatin<sup>13</sup> 80 years ago, seems to be better founded than any other. The exact investigations of v. Fellenberg<sup>14</sup> on the iodine-content of food and drinking-water in the goitre-free La Chaux de Fonds, in comparison with the conditions in the goitrous Signau in Emmenthal showed the far greater iodine intake in the goitre-free La Chaux de Fonds. McClendon and Hathaway have shown the inverse relation in North America between goitre and iodine in food and drink, and Hercus, Benson, and Carter<sup>15</sup> have demonstrated the relationship between iodine in soil, plants, and animals, the iodine content of human food being chiefly dependent on the soil from which the population is indirectly nourished. The introduction of iodine admixture to the salt in goitrous districts has given good results, and the evidence is already becoming overwhelming that iodine deficiency plays the foremost rôle among the causal factors of endemic goitre.

Although iodine deficiency is the most important causal factor in goitre, other factors may also influence the size of the thyroid gland. Thus Sahovic and Frajnd<sup>16</sup> observed that rabbits fed on cabbage and potatoes developed a bigger and heavier thyroid and showed less increase in weight than those fed on ordinary food, and Webster<sup>17</sup> came to the same result, that cabbage contains a goitrogenous substance, probably a cyanure.

The theory of iodine deficiency conforms well with our findings in Iceland, where iodine intake seems to be unusually great. Iodine is chiefly contained in the sea, and we know that sea-plants and fish are the richest sources of iodine in human food. Icelanders, and particularly the inhabitants of Reykjavik, whence our material is chiefly derived, are great fish-eaters, and as all the population of the country lives along the coast, within 50 miles from the sea, the air must contain relatively much iodine. The New Zealand investigators have confirmed Chatin's findings, that igneous rocks are richer in iodine than sedimentary rocks, and as soil rich in alkaline earth carbonates is particularly active in this respect, the Iceland soil is probably rich in iodine, being alkaline and of volcanic origin.

According to McClendon<sup>18</sup> the Japanese are great consumers of iodine rich seaweeds, and he attributes to that fact the low weight of their thyroids and the absence of goitres. Seaweed was up to this century

eaten in various parts of Iceland, but its consumption has practically ceased now, so that it cannot be alleged to be of importance in this connexion here. The drinking-water in Reykjavik is exceptionally pure spring water, containing minimal amounts of mineral salts and is practically sterile. Cabbage consumption is minimal compared with other European countries and potato consumption similar if not slightly less than on the continent.

These factors might be of some influence, although fish-eating is probably the all-important factor. Nicolaysen and Lunde, investigating iodine in urine among Norwegians, found people who had one to three fish-meals a week excreting almost double the amount found by those who took no fish.

**ATHERO-SCLEROSIS**

Another thing which is striking when autopsies here are compared with what one sees on the continent is the rarity of athero-sclerosis. I have tried to compare our findings with those of other pathologists, but such comparison involves a considerable difficulty, as atheromatosis (= lipoid infiltration) and athero-sclerosis (= lipoid infiltration + calcification) are not always clearly distinguished. In our cases we have noted as atheromatosis lipoid thickenings of the intima and as athero-sclerosis where hard, calcareous patches were found. From our records I find the following figures on changes in aorta:—

Age.	Athero-sclerosis.	Athero-matosis.	No changes (smooth aorta).	Not noted.	Per cent. athero-sclerosis.	
					(a)	(b)
30-39	1	1	16	20	11.0	5.3
40-49	2	1	19	26	13.7	6.3
50-59	6	1	15	19	31.8	17.1
60-69	9	2	11	12	50.0	32.4
70-79	14	—	1	5	93.0	70.0
80-89	3	—	—	3	—	—

The true percentage must lie somewhere between those in columns (a) and (b) in which the "not noted" cases are excluded and included respectively.

For comparison the findings of atheromatosis in fallen soldiers by Mönckeberg<sup>19</sup>:—

Years of age.	Showing athero-sclerosis.		
	Cases.	Number.	Per cent.
Under 20	.. .. 14	.... 5	.... 36
" 25	.. .. 45	.... 34	.... 76
" 30	.. .. 20	.... 18	.... 90
" 35	.. .. 15	.... 12	.... 80
" 40	.. .. 16	.... 16	.... 100
" 45	.. .. 1	.... 1	.... 100

Aschoff adds that other pathologists have found similar figures. Rosenthal<sup>20</sup> studied athero-sclerosis of aorta in 500 autopsies in Chicago in white and coloured persons. The negroes showed higher figures of sclerosis than the whites. As this author has divided his cases into three groups, (1) those with smooth aortas, (2) slight athero-sclerosis, and (3) severe athero-sclerosis, his findings are comparable with ours. The following Graph shows athero-sclerosis found by him in 306 whites and our findings, whereby our higher figures are taken (from column (a)).

This graph shows the great difference between athero-sclerosis in Iceland and Chicago, and, as above mentioned, the figures for other countries do not appear to be lower than those for Chicago. It must be noted that in most of our cases, up to 70 years of age, the sclerosis found is only slight, or a few calcareous patches in the aorta.

**DISCUSSION**

Although our material is not yet great, it is evident that the Icelandic population has (1) an unusually

small thyroid gland, and (2) an unusually low rate of athero-sclerosis of the aorta. Athero-sclerosis of other arteries is also relatively rare. The question arises whether there is a causative relationship between the small thyroid and the low sclerosis-rate. Experimentally athero-sclerosis can be produced, in rabbits, by injection of adrenaline (Josué<sup>21</sup>) and by feeding with irradiated ergosterol (vitamin D). Liebig<sup>22</sup>

Percentage of athero-sclerosis found post mortem at various ages in Chicago (Rosenthal) and Reykjavik (Dungal).

administered diodol to rabbits during the feeding with cholesterol and thereby prevented or diminished atheromatosis in aorta and liver. Binet<sup>23</sup> has shown that potassium iodide and albumin-iodine have the same effect. Murata<sup>24</sup> has shown that atheromatosis may be prevented in rabbits by feeding thyroid gland substance. On the other hand, Pusch has shown that arterio-sclerosis is four times as frequent with goitres as with non-goitrous glands.

Probably the explanation for these conditions in Iceland is the abundance of iodine in our food, particularly the fish, which is consumed in relatively great amounts, but partly also by the iodine in air and soil which in all probability is great. In this connexion it may be mentioned that the Icelandic people ranges high in physical and mental powers. The question then arises whether the normal weight of the thyroid gland is not lower than that generally accepted, and whether a low degree of iodine deficiency is not more widespread than we think it is.

**SUMMARY**

The weight of the thyroid gland in Icelanders between 20-50 years of age is for males 14.9 g. and for females 11.3 g. Average weight for 57 persons over 20 years of age was 13.3 g. Athero-sclerosis in the population is unusually rare, and it is probable that abundance of iodine in food, soil, and air is the cause of both these phenomena.

## CLINICAL AND LABORATORY NOTES

**SUBCUTANEOUS EMPHYSEMA  
OCCURRING SPONTANEOUSLY IN A CASE OF  
PULMONARY TUBERCULOSIS**

BY BRIAN C. THOMPSON, M.D. Camb.

ASSISTANT TUBERCULOSIS OFFICER, DURHAM COUNTY  
COUNCIL

THE patient is a man aged 37, known to have been suffering from pulmonary tuberculosis since an initial hæmoptysis in 1930. He has twice been in sanatoria, and when last discharged in July, 1935, had extensive, rather chronic involvement of the upper halves of both lungs, with a large cavity in the right apex and tubercle bacilli in his sputum. His condition tended to deteriorate about the beginning of 1936, when he steadily lost weight and complained of abdominal symptoms.

At 1 A.M. on April 3rd, while sitting by the fire, he was seized by a pain in the right side and a "freezing" sensation which caught his breath. He felt ill and went to bed, and about an hour later became conscious of a fullness in the neck, which by daylight had become so pronounced that he thought he had "caught the mumps." He called in his private doctor, who found that the swollen tissues gave on palpation the crackling sensation characteristic of subcutaneous emphysema.

I was not at once informed of the condition and did not see the patient until April 8th, when the emphysema had reached its maximum. The bloated appearance of the patient was most striking, and crepitus was elicited over an area extending from both sides of the face as far as the temples, over both sides of the neck anteriorly to the second rib on the left and to the costal margin on the right, posteriorly to the angle of the scapula on the right, including the axilla and upper six inches of the right arm. There were no physical signs of pneumothorax and the patient seemed fairly comfortable. From that time the infiltrating air began to subside, leaving the neck first and the right side of the thorax last. On April 21st no crepitation could be felt and the patient expressed himself "fitter than ever since leaving the sanatorium." The X ray appearances at this time showed no striking changes from a previous film taken a year before. There was no sign of any pneumothorax. Now,

about six weeks later, the patient is clinically in about the same condition that he was nine months ago. His alarming experience has left no obvious ill-effect. He himself believes that it has done him good.

Spontaneous subcutaneous emphysema, as distinct from the interstitial emphysema which may occur following external trauma, surgical operations (especially tonsillectomy<sup>1</sup>), and the induction of artificial pneumothorax,<sup>2</sup> is a not infrequent complication of parturition<sup>3</sup> and of acute respiratory disease. It was found in 11 out of 1701 cases of influenzal bronchopneumonia during the 1918-19 epidemic,<sup>4</sup> and has from time to time been reported in connexion with bronchial asthma,<sup>5</sup> pulmonary emphysema, and acute pneumonia, particularly during childhood,<sup>6</sup> often with a fatal termination.

As a complication of pulmonary tuberculosis it is said by Fishberg<sup>7</sup> to be "very rare." It was first described in this connexion in 1919 by Chifoliau,<sup>8</sup> and only three subsequent cases appear to have been reported, by Pick<sup>9</sup> in 1925, by Meade and Stafford<sup>10</sup> in 1930, and by Dobbie in this journal last February.<sup>11</sup> In Chifoliau's case, air was liberated into the subcutaneous tissues from a superficial cavity adherent to the chest wall, and from thence spread over the thorax. Dobbie's case and Pick's case were clinically similar to that at present under discussion; in the former dyspepsia proved fatal 58 hours from onset. The case of Meade and Stafford was preceded or accompanied by the formation of a spontaneous pneumothorax on the left side; this was relieved by thoracotomy, after which the subcutaneous emphysema spread so widely and so embarrassed the patient that it became necessary to release the air by multiple skin incisions, which was followed by tardy recovery.

Theoretically, there are two possible routes by which air may pass from the lung to the subcutaneous tissues:—

(1) Intrapleural, through a breach in the visceral pleura and subsequent perforation of the parietal pleura from the pneumothorax so formed. An extravasation through adhesions between the pleurae, as in Chifoliau's case, is not, strictly speaking, intrapleural.

(2) Extrapleural, in which air escapes from the lung along the course of the blood-vessels to the posterior mediastinum and from thence to the superior mediastinum, to appear first in the lower part of the neck. This route was demonstrated by Berkeley and Coffin<sup>4</sup> at autopsy on several of their cases of broncho-pneumonia. At the peripheral lung border they found ruptured emphysematous bullæ, from which "air streaks" led through the vessel sheaths; on squeezing the lung under water with the pleura intact, bubbles of air appeared profusely at the hilum.

Spontaneous subcutaneous emphysema arises in the majority of cases probably by the extrapleural route; this can explain satisfactorily most cases due to non-tuberculous disease and also Pick's and Dobbie's cases. Meade and Stafford suggested that in their case the air escaped both intra- and extrapleurally, that the pneumothorax restrained by pressure any further passage of air to the hilum, and that relief of this pressure by thoracotomy allowed the extrapleural leakage to proceed.

In the present case, widespread tuberculosis in both lungs must have caused subpleural erosion at some point. Instead of perforating the pleura, the formation of a spontaneous pneumothorax, the air passed by vessel sheaths to the mediastinum, and thence to the subcutaneous tissues of the neck. Heal-

## TORSION OF THE VERMIFORM APPENDIX ASSOCIATED WITH PREGNANCY

BY GERALD FLATLEY, M.B. Belf.

RESIDENT MEDICAL OFFICER IN THE MATERNITY DEPARTMENT,  
MILE END HOSPITAL, LONDON

ON mechanical grounds alone, from its position and structure, the vermiform appendix appears to lend itself to torsion. The condition is, however, exceedingly rare, and a careful search reveals only a single case reported in English—that described by McFadden<sup>1</sup> in 1926. In neither English nor continental medical literature have I been able to trace its occurrence during pregnancy. In view of this, the following case-note may be of interest.

A primigravida, aged 22, was admitted to Mile End Hospital on Feb. 11th, 1936, with the history that she had been awakened 38 hours before by very severe periumbilical pain. She had vomited several times without relief. The pain was still present, had not radiated, and

<sup>1</sup>McFadden, G. D. F.: *Brit. Med. Jour.*, 1926, **ii**, 1223.

at the time of admission was but slightly less severe than at onset.

*Examination.*—Well-nourished young adult. Pulse-rate 100. Temperature 100° F. Blood pressure 128/80 mm. Hg. Slight malar flush. Tongue very furred and dry. Nothing abnormal noted in thorax.

Abdomen: uterus 26 weeks' size—i.e., corresponding to the period of amenorrhœa. Left occipito-anterior presentation; head not fixed. Fœtal heart heard, the rate being 130. Great tenderness on either side of the umbilicus, right rather more than left, and associated with some rigidity of the right rectus.

*Diagnosis* appeared to rest between acute appendicitis and red degeneration in a small intramural fibroid.

A blood count by the Mile End Group Laboratory just before operation gave a white cell count of 18,000 per c.cm., of which 91.5 per cent. were polymorphonuclears, 6.5 per cent. lymphocytes, 1.5 per cent. monocytes, and 1.5 per cent. basophils. The Schilling hæmogram gave a toxic index of 0.7.

*Operation.*—Abdominal section was decided upon, and after premedication with morphine sulphate gr.  $\frac{1}{4}$  and hyoscine hydrobromide gr. 1/100, a right lower paramedian incision was made under spinal anaesthesia (per-caine 14.2 c.cm.). The uterus was normal. The cæcum was brought into the wound and the appendix, pre-leal in position, was found to have become twisted through two and a half turns about a point half an inch from the proximal end. The distal portion of the appendix, 3 $\frac{1}{2}$  in. long, was gangrenous. The appendix then proceeded to unwind itself slowly without mechanical aid. Appendectomy was performed and the abdomen closed.

Microscopical investigation of the appendix by the L.C.C. Central Histological Laboratory showed "purulent peritonitis over a dilated, necrosed, and engorged appendix."

Despite intensive medication with sedatives, labour began and the patient delivered herself of a 27 weeks' miscarriage eleven days after operation. Convalescence thereafter was quite uneventful.

I am indebted to Dr. Alan Randle, superintendent of Mile End Hospital, for permission to publish this case.

## REVIEWS AND NOTICES OF BOOKS

### Treatment of Venereal Disease in General Practice

By THOMAS ANWYL-DAVIES, M.D., B.S., M.R.C.P. Lond., Director, L.C.C. Whitechapel Clinic; Consulting Venereologist to the L.C.C.; Lecturer in Venereal Diseases to London Hospital Medical College. London: John Bale, Sons and Danielsson Ltd. Pp. 202. 7s. 6d.

ONE of the disadvantages of increasing specialisation in medicine is the danger that the general practitioner may lose touch with modern methods of treatment in certain highly specialised branches, especially when, as in the case of venereal diseases, references to these subjects in current medical periodicals are relatively infrequent. This small and readable manual from an authoritative source should do much to counteract this tendency in relation to the treatment of these infections.

Dr. Anwyl-Davies has succeeded in compressing a remarkable amount of important matter into a limited space, and has presented facts in a clear and interesting way. The chapters dealing with the treatment of syphilis are particularly good. The various remedies are enumerated and discussed, and the methods of administration described. Principles of treatment, dangers, and precautions are well set out; and practical schemes of treatment adapted to the individual needs of patients and to the different stages of the disease are suggested. On the more

controversial subject of gonorrhœa description is wisely confined to the methods which the author himself favours, but in respect of these practical detail is not spared. The treatment of less common venereal infections is briefly summarised.

Certain blemishes detract from the general excellence of the work; among them is a tendency to the use of a loose terminology, especially in reference to pathological and metabolic processes. "Paralysis of the liver" is not a scientific or even an accurate description of the toxic effects of the arsenobenzenes upon the liver cells; and the statement that "alcohol . . . reduces the antigenic properties of the blood," even if it were correct, is hardly relevant to its context. Occasionally, too, the author's enthusiasm for some particular form of treatment outruns his discretion in recommending this treatment for general use. For example, however good may be the results obtained by experts, the practice of treating acute gonococcal cervicitis and salpingitis by the intra-uterine instillation of glycerin would be dangerous in unskilled hands. The statement that the dosage of non-detoxicated gonococcal vaccines varies from 5000 million organisms to a maximum of 80,000 millions is probably the result of a printer's error, but it might lead to unfortunate results if accepted and applied by the practitioner. Apart from such errors, which are very few in number, this book is a most welcome addition to the small number of practical manuals on this subject.

## Poverty and Health

By G. C. M. M'GONIGLE, M.D., D.Hy., D.P.H., and J. KIRBY, M.R.S.I. With a foreword by Sir F. GOWLAND HOPKINS, O.M. London: Victor Gollancz Ltd. 1936. Pp. 278. 6s.

It is right and necessary that medical men working in the distressed areas should make known their views on unemployment. Dr. M'Gonigle is medical officer for Stockton-on-Tees, and his book, written in collaboration with Mr. J. Kirby, is intended to bring the problem of malnutrition more urgently before profession and public. After pointing to the unsound physical condition of the population, as indicated by the unfitness of recruits to the Services, the authors turn to the state of the children and provide an interesting chapter on the examination of child welfare records. The essential part of the book, however, is based on Dr. M'Gonigle's well-known observations on a population removed from a slum area to a new housing estate. By this translation the rents of the families were increased by 4s. 4d. per week, thus reducing the margin available for food. To malnutrition is attributed the subsequent increase in the crude death-rate from 18.75 to 26.71, and "approximately a four-fold increase on a normal expected death-rate." The objection to this argument is that the findings are based on too small a sample. The population at risk was only 710, on which population the crude rates quoted show 13 and 19 actual deaths—figures which are insufficient for valid deductions. Incidentally the actual causes of death might well have been set out so that their relation to nutrition might be considered.

This reliance on small samples affects also other of the conclusions drawn. Thus comparisons are made of death-rates of employed and unemployed based on populations of 1564 and 1572. There are shown crude death-rates of 25.47 for unemployed and 17.1 for employed, and standardised rates of 29.29 and 21.01, and these latter are compared with expected rates of 8.75 and 8.53. Dr. M'Gonigle and Mr. Kirby may well refer to the figures as startling; but are they justified? For any validity the calculation needs to be made from a much wider basis. The conclusions have to be set against such a statement as the following, from the Registrar-General's Decennial Supplement England and Wales, 1931 (Part I.).

"The following comparative figures (Table P) indicate the relation of the recent experience in these sections to that disclosed by the 1921 investigation. It will be seen that in the Northumberland and Durham County Boroughs there has been a substantial improvement at all the ages shown in the table except at age 20 in the case of females. This is a matter of high importance as proving that the death-rates in the worst years of the economic depression and in an area ranking among those most severely hit by that depression exhibit no increase. On the contrary the mortality experience in this section is lighter than that disclosed by the previous decennial investigation, and on the analogy of the national experience there is reason to believe that if research were carried back sufficiently far it would be found that in the years 1930-32 the mortality experience of the County Boroughs of Northumberland and Durham was lighter than that of this area in any corresponding period in the present century."

Table 50 of the book sets out various income scales and corresponding death-rates as means of a four-year period. The figures show a variation of crude death-rate from 30.96 at 25s. to 35s. per week to 9.00 at 75s. or over per week, and a variation of standardised rates from 25.96 to 11.52. The populations in the five groups vary from 1187 to 132. The

population in the highest grade is 140, and the crude death-rate is 9.00, which represents 1.26 deaths per annum. We do not doubt the accuracy of these data, but it seems to us that, with so small a population observed over so short a time, it cannot be concluded that the observed numerical differences represent real differences in the mortality of the contrasted categories. The figures are suggestive, but the deductions must be tentative.

Less controversial are the chapters devoted to food and family budgets and expenditure. These show an intimate knowledge of social conditions and the detailed analysis of expenditure merits careful perusal. They are a revelation of how the poor live. The various necessary items of expenditure apart from food are given, and Tables 46 and 47 show food expenditure in ingredient value and in quantity. The main point brought out, and which has been elsewhere emphasised, is the shortage of protein, and no one can doubt the importance of laying stress on this, especially in relation to the growing organism. It may be noted, for example, that the weekly amount of fresh milk purchased per man-value in the lowest income group was only 0.55 pints; this may be related to C. M. Burns's investigation of the consumption of milk by 1000 families in County Durham which showed "the figures for whole milk purchased are appallingly low, ranging from 0.25 pints to 0.005 pints per head per day."

As we have said, the conditions of the distressed areas must somehow be brought home to the mind and conscience of the more favoured population. Too many of us have still a quite inadequate appreciation of the circumstances; Jarrow and Oxford-street are in different worlds. It is not surprising that the authors of this book, confronted by the problems presented in a district of heavy and continued unemployment, should be oppressed by their urgency; probably they could say with the Psalmist "The zeal of thine house hath eaten me up." But their deductions seem to us incompletely justified by their data. The book therefore should be read, but it should be read critically.

## The Operations of Surgery

By R. P. ROWLANDS, M.S., F.R.C.S., late Surgeon to Guy's Hospital; and PHILIP TURNER, B.Sc., M.S., F.R.C.S., Consulting Surgeon to the Hospital. Eighth edition. Vol. I. London: J. and A. Churchill Ltd. 1936. Pp. 1045. 36s.

HOWEVER skilful he may be the young surgeon must often be conscious of his lack of experience; not so much when performing an operation for the first time as in selecting the cases suitable for surgical treatment and avoiding the "wrong 'uns." It is in this respect that the advice of a senior colleague may be so helpful, and the most valuable attribute of "Rowlands and Turner" is that it provides a written substitute for the wise counsellor. In the final production of this volume Mr. Philip Turner has been deprived of the collaboration of Mr. R. P. Rowlands, who died while this eighth edition of the work was in course of preparation. He has been fortunate in obtaining the assistance of Mr. W. H. Ogilvie and Mr. Grant Massie, who have undertaken the revision of the chapters on the vertebral column and the lower extremity, and a determined effort has been made to maintain the high reputation so justly enjoyed by the earlier editions of "Jacobson." The sections of the book

which deal with the surgery of the limbs required very little revision, and the new matter added by Mr. Grant Massie on the lower extremity has been clearly set out, though it might have been an advantage to include rather more detail about the indications for the orthopædic operations, and fuller descriptions of those for various forms of talipes.

When bringing out another edition of a well-established text-book it must be hard to decide how much to keep of the old and how much to add of the new in surgery. For the most part Mr. Turner's decisions have been wise, and adequate accounts are given of plastic operations, recent experience of the use of radium in carcinoma of the tongue and of the breast, cervico-thoracic ganglionectomy, and the recognition and removal of tumours of the parathyroid gland. On the other hand, commonly accepted innovations in the surgery of cervical rib, ankylosis of the jaw, thyroglossal cysts, and the thyroid gland are omitted; the chapters on the brain and on the thorax are lamentably out of date; and it is high time that longitudinal incisions in the neck should be condemned in any but the most exceptional circumstances. Criticism must also be directed at the references to the literature which supply volume and page but no date. A large number of these references are very old, and it is essential that the reader should be able to distinguish them from the more recent ones. The book has been to so many surgeons a wise and trusted friend that those who are entrusted with maintaining its fine traditions have a special responsibility.

### A Manual of Physics

Fourth edition. By J. A. CROWTHER, Sc.D., F.Inst. P., Sometime Fellow of St. John's College, Cambridge; Professor of Physics in the University of Reading. London: Humphrey Milford, Oxford University Press. 1936. Pp. 585. 14s.

THIS manual, now in its fourth edition, has an established place in the presentation of elementary physics. The new features now incorporated lie for the most part in the electrical section where good accounts are given of methods of production of X rays and their physical properties, and of natural and artificial radio-activity. Prof. Crowther has found it necessary to enlarge the section on alternating current, and the result is a very readable and instructive account of electro-magnetic induction and the practical applications which have led to the devising of such a variety of different instruments. The book can be recommended without qualification; it is attractively written, comprehensive, and accurate.

### Introduction to Human Parasitology

Fifth edition. By ASA C. CHANDLER, M.S., Ph.D., Professor of Biology, Rice Institute, Houston, Texas. New York: John Wiley and Sons, Inc.; London: Chapman and Hall Ltd. 1936. Pp. 661. 25s.

THE scope of this book is wider than that of most works on human parasitology. The subject has been divided into three main sections, dealing respectively with protozoa, helminths, and arthropods. Within these sections the chapters have been arranged in a systematic manner, either from the standpoint of zoological classification or from that of effects on the host. While it has obviously not been the author's intention to give a complete account of

all the parasites dealt with, detailed descriptions and figures have been supplied where two important species have to be differentiated—e.g., between *E. histolytica* and *E. coli*, *T. solium* and *T. saginata*, and *X. cheopis* and *X. astia*. Additions made during the last few years to our knowledge of human parasitology have been numerous and important. Particularly extensive changes have been required in many chapters of this book, notably those dealing with spirochaetes, amœbæ, malaria, rickettsias, flukes, strongyloides, filariæ, and myiasis; and in many places complete rewriting and rearrangement have been necessary in order to give an adequate and well-coördinated presentation. Throughout the book special emphasis has been laid on the biological aspects of the subjects. Considerable space is devoted to life-cycles, epidemiological factors, and inter-relations of parasite and host. Specific and detailed directions for the treatment of the parasitic diseases have been excluded, but the underlying principles of treatment and prevention are discussed. Since it is difficult to go very far into such a vast subject as parasitology within the limits of one book, Prof. Chandler has included a list of the leading journals and standard works which cover the field. His enthusiastic outlook is refreshing. The book is well produced and clearly printed with numerous effective diagrams.

### Psychology and Religion

By DAVID FORSYTH, M.D., D.Sc. Lond., F.R.C.P., President of the Section of Psychiatry, Royal Society of Medicine; Consulting Physician to Charing Cross Hospital. London: Watts and Co. Pp. 221. 7s. 6d.

THE discussion of the conflict between science and religion has moved far since the days of Huxley. The earlier concentration on the historicity of the Bible, the testimony of the rocks as against the cosmology of Genesis has more or less ceased, at least outside fundamentalist circles. But with the challenge of anthropology and psycho-analysis the problem has assumed a new and more cultural guise. Religion could stand up to the theory of the evolution of the species, but the real test is whether it can stand firm when psychology and anthropology allege that man's moral and social nature evolves from lower to higher forms. The theory that man passes from a religious to an artistic-philosophic and thence to a scientific level of enlightenment was the view of Auguste Comte. But he did not have a Tylor and Frazer, a Westermarck and a Freud to give chapter, verse, and punctuation to support his views.

In this book Dr. Forsyth builds almost entirely on Freud's theories of the development of the child mind and his theory of social origins. No one will deny that Freud's œdipus complex has illuminated the dynamics of the mind and incidentally the origin of society and its usages. But while the Cyclopean family is even to Freud a speculative concept, it is not easy to accept the corollaries of this idea, as applied to human society and its institutions. Moreover, it is not logically sound to equate the imaginative ideas of simpler peoples with the illusory. Religious ideas and folk practices were the ways in which the simpler peoples dealt with the world and their own relations; it was in short their social science. It must be agreed, however, that the abundant use of magic and of some forms of religion is no longer serviceable to humanity and can be positively harmful; for example, its extension into patriotism can

have devastating international effects. Furthermore, Dr. Forsyth is not always up to date in his psycho-analytic data, and perhaps on this account he makes a simple process of what is now known to be a very complex one even in the child mind—i.e., magical thinking and its fructifying effects. Religion is shedding and will doubtless contrive to shed many of its primitive notions, and its anthropomorphisms. But there are some who will for epochs to come continue to feel awed by nature and moved by that "oceanic feeling" which Freud claims he has never felt.

### Cystoscopy and Urography

Second edition. By JAS. B. MACALPINE, F.R.C.S., Hon. Surgeon and Surgeon in charge of the Genito-urinary Department, Salford Royal Hospital, Manchester. Bristol: John Wright and Sons, Ltd.; London: Simpkin Marshall Ltd. 1936. Pp. 478. 30s.

NINE years have elapsed since the first appearance of this book, and nine years is a long period in the history of urology. Many new methods of examination have been introduced, the most notable being excretion urography. These advances have necessitated the inclusion of three entirely new chapters dealing with excretion urography, pyeloscopy, and pelvic resorption. Of these the first is the most important, pelvic resorption being mainly of scientific interest, and pyeloscopy a method of examination which, though excellent in principle, is difficult in practice. As the author points out, the presence of a foreign body (the opaque fluid) in the ureter excites efforts at expulsion, and the appearance of the pelvis and calyces under these artificial conditions cannot be regarded as physiological. Moreover, few clinicians have the time or the experience necessary to interpret the constantly and quickly changing shadows seen on the fluorescent screen.

Mr. Macalpine writes clearly, and does not overload his text with theories or quotations from other authorities. His book is eminently practical, and with its help those who have limited experience of cystoscopy and cystoscopic methods will be able to improve their technique and increase their knowledge of cystoscopic conditions. The coloured plates are of a high order, so also are the reproductions of pyelograms illustrating the section on pyelography and excretion urography.

### Disease in Childhood: The First Year

*A Clinical Study.* By ROBERT S. FREW, M.D. Edin., F.R.C.P. Lond., Physician to the Hospital for Sick Children, Great Ormond-street. London: Macmillan and Co., Ltd. 1936. Pp. 669. 30s.

THE age-incidence of disease is a study which has hardly received the attention it deserves, and in reading the preface to Dr. Frew's work one is struck by the good fortune of a physician privileged to see all out-patients in age order for a period of seventeen years. Unfortunately, however, it soon becomes obvious that when the first year of life is subdivided into three age-periods even statistics based on 8823 consecutive cases under 12 years of age, provide a quite inadequate basis for discussion of any except the commonest disorders of childhood. Dr. Frew has not, in this book, supplemented his own experience to any considerable extent by quotations from recent medical literature. This is the more unfortu-

nate because his own views on pædiatric pathology are unconventional. He attributes many of the disorders of childhood, with the exception of tuberculous meningitis, to a condition which he calls "hyperphlebæmia." It would be wearisome to enumerate all the diseases, from laryngismus stridulus to early pulmonary fibrosis, and from cretinism to celiac disease, which he finds due directly or indirectly to this cause. "A bewildering array of clinical manifestations" seems, under the circumstances, a cautious understatement. With sledgehammer logic the author proceeds to apply an Alice-in-Wonderland system of pathology to treatment, with results such as the following: "If, when the baby is born, . . . he is suffering from 'white asphyxia,' the cord should be severed without ligaturing and bleeding promoted by every available means" (p. 144). Similarly after concluding that a failure of the ductus venosus to close at birth is the most likely explanation of "status lymphaticus" (with the cautious proviso that when the opportunity arises, this point will naturally be investigated with great interest), he says: "If this be the ætiology of the disease, then in cases where a thymic shadow is found, I imagine it will not be beyond the skill of the surgeon to ligature the ductus venosus under local anæsthesia before a general anæsthetic is administered" (p. 564). It is difficult under the circumstances to appreciate the few jewels that undoubtedly exist in a somewhat fantastic setting. The book is well printed and contains a number of excellent illustrations.

### Treatment of Fractures in General Practice

*Pocket Monographs on Practical Medicine.* Second edition. By W. H. OGILVIE, M.D., M.Ch., F.R.C.S. London: John Bale, Sons and Danielsson. 1936. Pp. 180. In two volumes. 2s. 6d. each volume.

WE welcome the second edition of these two small green volumes on fractures. It is an achievement to have compressed so much information into small compass and yet to have produced a text easy and pleasant to read. The first part of the work, which covers the 58 pages of Vol. I., is devoted to the general principles of fracture treatment. The enumeration of the headings and subheadings from page 21 onwards still seems to us somewhat unsatisfactory; in all other respects the meaning is clear and the description of methods of treatment concise and easy to follow. From the practitioner's point of view it is an advantage that Mr. Ogilvie describes only methods of proven value, the apparatus for which is readily available. For fractures of the upper limb, for example, the moulded plaster-of-Paris splint is described and illustrated. Skeletal traction is recommended in fractures of the lower limb, but methods of skin traction are also described, and the practitioner is advised to use these where the case is being nursed under less ideal conditions. It is interesting to find an account of a serviceable method of treatment by continuous traction of fractures of the neck of the femur; this is recommended for use in very feeble patients. The operation described for this fracture is by the Watson Jones modification of the Smith-Petersen's pin fixation. In general, however, open operation for fractures is properly relegated to a secondary position.

This excellent monograph is worthy of a place in the surgery of every practitioner and in the pocket of every student.

# THE LANCET

LONDON: SATURDAY, JUNE 13, 1936

## CARE FOR THE DEAF

ON Thursday the National Institute for the Deaf celebrated its silver jubilee with the opening by H.R.H. the Duke of YORK of new headquarters at 105, Gower-street, London, W.C.1. An appeal is being made by Lord CHARNWOOD, the president of the Institute, for larger support of a movement which during its 25 years of existence has proved the necessity of the objects for which it exists and justified the energy with which the officiate has laboured to overcome great difficulties. The first of those difficulties is the general apathy, due to lack of information, displayed by the public in regard to the position of the deaf in the community. Year by year at annual meetings of the Institute the case of the deaf has been brought forward with the intention to show how vastly the deaf can help themselves, if only they meet with help from their more fortunate brethren, and to illustrate how large is the range of activities along which the deaf can prove themselves valuable citizens, when the courtesy and patience necessary to bring about normal intercourse are extended to them. Reasoned advocacy along these lines has produced during the existence of the Institute practical results. Associations made up of representatives of deaf societies and of public authorities have been established in many areas, covering indeed England and Scotland, and similar centres it is to be hoped will soon be established in Wales and Northern Ireland. Such public and private movements have produced many beneficial results, among others the vital one of the placing of many deaf in employment. But the aims of the Institute cannot be fully realised till adequate provision is made for the training of the adolescent deaf, for their re-training when necessary, and also for the replacing in suitable work of adults who have become deaf through disease or accident. Lord CHARNWOOD, an untiring public servant, points out in his jubilee appeal that these developments will entail the strengthening of voluntary societies to fit them for larger responsibilities, while districts in which the interests of the deaf are still unrepresented by any society must be stimulated to play their part.

No special legislation exists to protect the interests of the deaf, apart from that which entitles deaf children to suitable education. Their cause has been the concern of the National Institute, a voluntary body, and of its affiliated associations and voluntary local societies. The Institute maintains three organisations for deaf women and working deaf boys, and acts as a clearing house for the work of the county associations. Its scope is largely administrative and will be found well set out in its publication "All About the Deaf."<sup>1</sup>

<sup>1</sup> London: The National Institute for the Deaf, 105, Gower-street, W.C.1. 1934. 1p. 122. 3s. 3d.

Here will be seen how the deaf are helped and how they may help themselves. And in this publication Lord CHARNWOOD draws the valuable if self-evident distinction between the case of those deafened through injury or disease and those born deaf, in whom the prevention of deafness has not to be considered. The only State inquiry into the conditions of the deaf made during the last 50 years was summarised in a report by the late Dr. EICHHOLZ in 1930. But this document, though embodying the result of the first investigation of the State into the needs of the deaf over school age, paid little attention to the needs of the deafened, who form a much larger class than the born deaf. The Institute desires to see the compulsory school age lowered to five years for children born deaf; for their investigations prove that, if speech is to be acquired by deaf-mutes in a way to fit them for playing their part in national life, it must be acquired young. Relegation of education until the age of seven is extremely unfortunate. Further an extension of suitable educational opportunities for school leavers is needed, while another just reform among the objects of the Institute is the granting of earlier old-age pensions to those who through deafness are unable to support themselves by their own labours. This would bring the treatment of the deaf into line with that of the blind, and to be deaf is as much a deprivation as to be blind. The sad case of the blind is spectacular; that of the deaf must go without public notice.

Other aims of the Institute, emphasised by Lord CHARNWOOD in his appeal, are, first, the maintenance for both sexes of hostels for the adolescent deaf similar to those for homeless deaf boys successfully established at Highbury; and, secondly, the establishment of homes to receive the adult deaf on the lines of the Institute's homes at Barrowford in Lancashire and Poolemead in Somerset. In these places the inmates are made happy through being able to communicate with one another and with the trained staffs; while to lessen the hardship of isolation—the heaviest burden which the deaf subject has to bear—the Institute has started lip-reading classes at its headquarters for the deafened generally. In these and other ways the headquarters of the Institute has become a clearing house for all matters connected with the deaf. In close touch with the principal deaf societies throughout the world, it has established with them a systematic exchange of the latest results of research into deaf problems of all kinds. Through a skilled staff and a medical committee of distinguished aurists; an executive committee on which are represented the regional associations, the London County Council, the associations of county councils, many municipal corporations and education committees, various local deaf societies, the National College of Teachers of the Deaf, and individual members of both Houses of Parliament, the Institute is in close touch with the Ministries of Education, Health, and Labour. It is thus able to combine research and organisation on a national scale with individual help to the deaf in all parts of the United Kingdom.

All this in 25 years. But much remains to be done. Probably there are some 40,000 deaf-and-dumb persons among us and perhaps two million seriously deaf. The helping of such a population is a gigantic task and at every step the Institute has been hampered in its efforts by lack of adequate funds. Its new headquarters, made necessary by the rapid growth of its services, should be freed from debt, and this burden now stands at £8000. But for the extension of its labours, if only along the lines already laid down, at least £50,000 is required. To find this sum the jubilee appeal approaches the public with confidence. It is after all a small sum that is asked for when compared with the benefits conferred on a section of society who especially deserve help from the community, if only because of the return which when helped they can make.

### MICE AND MEN

ALL who are interested in epidemiology and scientific medicine will welcome a report by GREENWOOD, BRADFORD HILL, TOPLEY, and WILSON, which has just been published by the Medical Research Council.<sup>1</sup> For nearly twenty years one or more of this team of statisticians and bacteriologists have been producing papers on the spread of epidemics under controlled conditions among herds of mice. In the present report they conveniently summarise the results of their previously published work and add some new observations, including an account of epidemics of the virus disease of mice known as ectromelia. It is possible here to mention only a few of the more important conclusions that are to be drawn from this continuous study of mouse infections. One of the most remarkable findings is that, although under certain conditions waves of mortality may be separated by quiescent periods, yet infection of a herd with *Bacillus aertrycke* (mouse typhoid) or *Pasteurella muriseptica* will never die out so long as fresh susceptible mice are added at intervals. The continuity of infection between separate epidemic waves is maintained by chronic infections among the more senior mice which have survived one or more waves of mortality. These survivors are nevertheless not permanently immune to the specific infection and will ultimately die of it if they remain in the infected herd. Their failure to establish a permanent immunity is somewhat unexpected in view of the usual assumption that repeated antigenic stimuli, natural or artificial, will always increase specific acquired immunity. In this connexion TOPLEY has shown that repeated injections of an *aertrycke* vaccine, after first raising the resistance of mice, are ultimately followed by a fall in the degree of resistance, as though the specific defence mechanism had been exhausted. If the mice entering an infected herd have previously been protected by inoculation their expectation of life is increased; but their artificial immunity—like that acquired by exposure—does not save them from eventually succumbing to the

specific infection. At the same time we must not allow the relative failure of "antityphoid" inoculation in mice to discourage the use of human anti-enteric vaccines; for, as the authors say, "neither war, nor the absence or breakdown of adequate sanitary control among a civilian population, is at all likely to produce conditions so severe as those to which our herds of mice are continually exposed." Hence it is the partial success in protecting mice that deserves chief emphasis. Nevertheless this work makes it easier to understand why we cannot hope ever to produce an absolute immunity against enteric diseases by inoculation alone and must always supplement it by adequate sanitary measures. The virus diseases present a rather different problem. In ectromelia, as one would expect from human epidemiological experience of viruses, a period of survival in an infected herd leads to immunity of a much higher order than is attained with the bacterial disease, mouse typhoid. In fact, mice which survive exposure to ectromelia for more than 65 days are found to have an expectation of life not very much less than that of normal uninfected control animals.

The authors of the report discuss whether the relatively greater resistance of the survivors of an epidemic is due to the selection of mice with a greater innate, or genetic, immunity or whether it is attributable to an acquired specific, or non-specific, resistance through contact and sublethal infection with the specific epidemic or other bacteria. Their experience leads them to favour specific acquired immunity as the most important factor, though others have also some weight in determining the length of survival in the infected herd. Thus a striking series of investigations revealed a class of mice that appeared to be immune to natural contact infection by virtue of some innate physiological peculiarity through which the bacilli were prevented from gaining access to their tissues. Such mice do not acquire a specific immunity; for when they are infected by parenteral injection of *B. aertrycke* they show themselves as susceptible as others. They present an interesting analogy to the children who do not catch diphtheria during years of close contact with carriers and cases and yet, despite this close contact, never develop diphtheria antitoxin in their blood, and are in addition very difficult to immunise artificially. The report also describes investigations showing that infectivity, the ease with which a parasitic microbe spreads from host to host, and virulence, the power of killing or injuring the host species, are separate characters which can vary independently, though as a rule highly virulent organisms are also more infectious than the average. Such bacteria, with a greater virulence and infectivity than ordinary endemic strains, may be termed epidemic strains. TOPLEY and GREENWOOD made an observation of fundamental biological significance when they were able to trace the evolution of an epidemic strain of *B. aertrycke* during an epidemic which had been initiated by a strain of ordinary virulence. The recent exacerbation in the prevalence and severity of diphtheria in certain localities is probably a

<sup>1</sup> Experimental Epidemiology. By M. Greenwood, A. B. Hill, W. W. C. Topley, and J. Wilson. Med. Research Council, Spec. Rep. Ser. No. 209. 1936. Pp. 204. 3s. 6d.

similar phenomenon, caused, in the first place, by the origin of epidemic strains of diphtheria bacilli—the so-called “gravis” and “intermediate” variants of *Corynebacterium diphtheriae*. The very nature of the problem makes it hard to obtain satisfactory evidence that differences in type of epidemic are in great part due to variation in the characters of the specific micro-organisms. L. T. WEBSTER, an American experimental epidemiologist of wide experience, has been so impressed by the negative results of his own investigations on this point that he is loth to admit that microbic variation plays any important part in the genesis of epidemics. It is therefore refreshing to hear TOPLEY and GREENWOOD and their colleagues boldly state that “variations in the character of a bacterial parasite may well be of decisive importance in the secular history of any epidemic disease.” Of course there is no implication in this statement that microbic variation is “a frequent concomitant of the evolution of a single epidemic wave.”

Assuming that bacteriophages are specific viral parasites of the corresponding bacteria, D'HERELLE and his followers' suggestion that human infections might be eradicated by the introduction of a suitable bacteriophage is not such a wild speculation as it may appear at first sight; it finds a parallel for example in the successful control of certain agricultural plant diseases by spreading the parasites of the pests themselves. So far, however, experimental epidemiology has produced no evidence in favour of the theory, and specific bacteriophages apparently have no influence on the course of a mouse-typhoid epidemic. In writing of this result TOPLEY and GREENWOOD cite the interesting “all or none” effect which was found by ANDREWES and ELFord, who working with a coli-phage mixture showed that there was no appreciable killing of the bacilli until the bacteriophage exceeded a certain concentration; but once this critical concentration of “phage” was reached the destruction of the colon bacilli was almost complete. Accordingly the failure to discover any effect of bacteriophages on mouse-typhoid epidemics does not necessarily mean that dramatic benefit might not follow the employment of other phages or other techniques. Negative results were also obtained in experiments planned to determine whether variation in the diet and its vitamin content would affect the mortality of infected herds of mice. These findings will cause surprise and disappointment among those who hope that the prevention of ill-health, including infectious diseases, mainly depends on raising the standard of diet and nutrition. But, so far as it has yet gone, experimental epidemiology supports the opinion of many field epidemiologists that diet is of little or no importance in determining the incidence or severity of epidemic diseases unless there is gross lack of vitamins, or frank starvation, among large sections of the population.

As is only to be expected, the investigations described in this report provide a model of the experimental and statistical technique involved in the analysis of herd diseases or epidemics. It

illustrates the caution and restraint that are required in interpreting the results of an experiment, the care needed in providing adequate controls, and the necessity of having a sufficient number of animals if, to quote the authors, the research worker is to avoid “basing conclusions upon data that will not bear their weight, and so adding further confusion to problems that are already obscured by a mass of ill-founded hypotheses.”

### THE BRITISH ASSOCIATION

BLACKPOOL has been chosen as the meeting-place of the British Association in September. It is a town whose civic authorities have made a successful study of modern amusement, and a scientific survey of Blackpool and of the Fylde, of which it is the centre, must have particular interest. The town has made remarkable experiments in street lighting and in the solution of the traffic problem which has baffled so many places which have the advantage of four points of the compass instead of three. Such a survey, which is now part of the Association's programme, will be an attractive number of a series which now includes York, Leicester, Aberdeen, and Norwich. The surveys of Leicester and Norfolk were in fact reprinted for educational use at the instance of the local authorities. Even a cursory examination of the programme for the Blackpool meeting suggests that the demand, especially vocal within the last two years, for the payment of more systematic attention to the bearings of scientific progress upon the welfare of the community, will be met this year. We do not yet know the precise content of Sir Josiah Stamp's presidential address on the evening of Sept. 9th, but as it will deal with the impact of science on society, we may be sure that it will include some of the economic and social problems which are troubling our minds. Since the centenary gathering in London in 1931 the annual meeting has never attracted less than two thousand enrolling members, apart from those who are drawn to one or other of its more popular items. The sectional transactions cover a large range of subjects, and this year for the first time a programme is indicated for those who would make an orderly study of scientific investigation in its bearing on the life of the community. Such communications, which are starred in the programme, include an address by Prof. Allan Ferguson on trends in modern physics, by Prof. J. C. Philip on the training of the chemist for the service of the community, by Brigadier H. S. L. Winterbotham on mapping of the colonial empire, by Prof. W. Cramp on the engineer and the nation, by Mr. J. Ramsbottom on the uses of fungi, and finally one by Prof. J. Hendrick on soil science in the twentieth century. Among the starred discussions are subjects such as economic problems affecting Lancashire, scientific problems of the poultry industry, road research and traffic problems, climate and health, social and cultural values of science, and, most appropriately, engineering problems of mass amusement. This closer coördination of work for the advancement of science is putting a severe strain on the economic position of the Association, and in the Five Years' Retrospect just issued it is pointed out that further endowment will be essential to consolidate the position it has attained at the close of its first century, and that expansion of membership and strengthening of financial foundations should be the object of all who would further its interests.

## ANNOTATIONS

## THE INITIAL STATE PRINCIPLE

It is a commonplace that a stimulus applied to a functional unit may evoke different results under different conditions. The experimental method eliminates difficulties due to the environment in so far as this can artificially be kept constant, but the immediate environment of a normally functioning organ is the rest of the body, and the experimenter can therefore never guarantee that the organ is more than approximately in the same state on different occasions. Most workers perform a "control" or dummy experiment in which the conditions are exactly the same as in the real experiment, with the exception that the stimulus is omitted. If the two experiments are run in parallel, the state of the organ in the control animal serves as a zero from which the response of the organ in the experimental animal can be measured. Only rarely is any interest evinced in the fluctuations of this zero; their existence is recognised purely in order that they may be fairly neglected in evaluating the response. On another page, Prof. S. Leites advances cogent reasons why these fluctuations should be regarded as of interest in themselves, and not merely as an experimental nuisance. Once the nature and "normal" magnitude of the response to a given stimulus have been determined, variations from the normal in individual cases should give information about the condition of the organ in question, if the relation between magnitude of response and the "zero state" is understood. This also seems a commonplace principle, and it is easy to cite instances, such as the sugar-tolerance test and renal functional tests, where it is used in practice. It is nevertheless true that a great deal more is known about the relations between all kinds of stimuli and their appropriate responses, than about the relations between the responses and the state of the organs which give rise to them. We take it for granted, for instance, that if an organ is in the same condition all the time the magnitude of the response varies as the strength of the stimulus. But if the response to the same stimulus varies from time to time, the most we can say is that the "condition" of the organ is also varying; no simple rule springs to the mind telling us just what alteration has taken place when the response increases or decreases. In certain cases we know from experience what has happened, but we have no general law.

The "initial state principle" of Prof. Leites represents an attempt to fill this gap, and recalls Weber's law of sensation. In its simplest form it states that the more excited an organ is to begin with, the less it will react to an exciting stimulus by increased activity, and the more readily will it react to a depressant by decreased activity. Prof. Leites points out various pitfalls which must be avoided in applying this principle, the chief of which is the temptation to employ a criterion of activity which is not strictly related to the stimulus. He points out its potential importance in investigating organs influenced in opposite senses by the sympathetic and parasympathetic systems respectively, in which a state of diminished activity may be due to overaction of one or underaction of the other. Numerous examples are given to illustrate the operation of the principle, but it must be stated that in one or two cases alternative explanations appear more likely, and the argument would have been

strengthened by their omission. Although it is not at present possible to accept without reserve any simple generalisation, there can be no doubt that the relation between response and initial state is a field of research which must be thoroughly explored in the near future. Perhaps the most exact investigation bearing on this point is that recently made by Prof. A. V. Hill and his co-workers<sup>1</sup> on the electrical excitation of nerve. They find that while the stimulus is rising to its full strength, the nerve is becoming less excitable, so that the adequacy of a stimulus depends not only on its ultimate strength, but upon the speed with which this is attained. Unless the stimulus rises more rapidly than the excitability of the nerve falls, it is ineffective. The mathematical expression of this relationship is by no means simple, and foreshadows difficulty in the treatment of systems where measurements cannot be made with the same degree of precision.

## PROGNOSIS IN CANCER OF THE BREAST

Nothing is more widely known about the prognosis of mammary cancer than that even after radical operation it is very much worse when there are axillary metastases. Dr. Channing Simmons<sup>2</sup> has found in a series that he has been studying that the average length of history when there was axillary involvement was six months, only three months more than the history of uncomplicated cases. This observation was contributed to a discussion on cancer of the breast held by the New England Surgical Society at Manchester, New Hampshire, and it is very significant. It means that, once carcinoma has appeared in the breast, it may be a matter only of weeks before it produces metastases. The prognosis of radical mastectomy is therefore entirely dependent upon early diagnosis, but, according to Dr. H. G. Jarvis, who opened the discussion, neither factor has shown definite progress in the last 15 years. Dr. Jarvis gave the figures for the Hartford Hospital. Out of a total of 320 cases, 266 (80 per cent.) were operable; 54 (20 per cent.) were inoperable, and at the end of five years all of these were known to be dead. Of the operable cases, 60 per cent. were dead and 40 per cent. alive. There was not a complete follow-up in the operable cases, only 82.5 per cent. having been traced. One contrast was significant; of 83 patients who had been operated on at a stage when cancer was limited to the breast, 42 were alive at the end of five years and without evidence of recurrence, whereas only 24 of 96 patients who had early metastases apparently limited to the axilla were alive and free of cancer five years after operation. So important does Jarvis consider early diagnosis that he believes that it is the responsibility of the surgeon to explore every case of tumour of the breast, even when the tumour is only suspected. Early and adequate treatment is not, however, the only factor in prognosis that Dr. Jarvis and the other speakers recognised. The pathologist at the Hartford Hospital has classed into three grades of malignancy 193 cases that have been followed for five years. In Grade I., that of lowest malignancy, 22 out of 23 patients without metastases were alive at the end of that time, and 5 out of 8 in those with metastases. Of 42 Grade II. patients without metastases, 28 were alive, but none with metastases had survived the five years. Grade III., the highest

<sup>1</sup> Proc. Roy. Soc. B., 1936, cxix., 305.

<sup>2</sup> New England Med. Jour., March 12th, 1936, p. 501.

degree of malignancy, was represented by 8 patients, none with metastases, of which 5 had survived for five years. In this series therefore the patient with a Grade I. carcinoma and no metastases had a more than 9 to 1 chance of living for five years. Grade I. cases with metastases had as good a chance of survival as those without metastases in either of the other grades—about 6 to 1. G. C. Wilkins and G. F. Dwinell quoted results from the Elliott Hospital. Of 62 patients whom they had traced since their operations during 1919–1930, 35 per cent. were now known to be well; 50 per cent. were “five year cures”; and 18 per cent. “ten year cures.” These two surgeons were convinced both of the inadequacy of clinical methods for diagnosing cancer in an early stage, and also of the importance of biopsy for every tumour of the breast. Pre-operative and post-operative radiation are employed by them as a routine, and they hope that the increased dosage now used will result in an improvement within the next five or ten years. Dr. Simmons, on the other hand, had employed pre-operative radiation in a series of cases and was not inclined to agree that it increased the prospects of cure. All the speakers preferred operation, whether combined with radiation or not, to radiation alone. They stressed how important it was that women should report any abnormality of the breast, and the responsibility that rested on the practitioner to countenance no delay in having the abnormality thoroughly investigated.

#### THE TRENDELBURG OPERATION FOR PULMONARY EMBOLISM

THE publication of a successful operation for embolism of the pulmonary artery by Valdoni<sup>1</sup> of the Alessandri clinic is of special interest, for this is the first successful operation of the kind in one of the Latin countries. Since Trendelenburg first performed the operation in 1908, it has been carried out successfully only in its country of origin and in Sweden (Kirschner 1, Meyer 4, Nystrom 2, Craaford 3).

Valdoni's patient was a man of 68 who was 14 days convalescent from an operation for a left inguinal hernia. While walking along a corridor he was seized by intense pain in the chest, fell to the floor and rapidly became unconscious. He was seen three minutes later and immediately removed to the operating theatre. In the Alessandri clinic a set of Trendelenburg instruments is kept in readiness, and seven minutes from the onset of the embolism the incision was made. The patient was deeply unconscious and anaesthesia was superfluous. The 2nd, 3rd, and 4th costal cartilages were removed, the pericardium incised, and the heart exposed. Irregular contractions of the organ were still present, and dilatation of the right heart and prominence of the pulmonary artery were apparent. The Trendelenburg sound was passed, a rubber tube introduced into the transverse sinus, and the pulmonary artery incised. There was a rush of dark-coloured blood with some fragments of clot. The embolus forceps were introduced and a 27 cm. clot was removed from the left branch of the pulmonary artery. At this point the patient stopped breathing and artificial respiration was begun. A second large clot was then removed from the right branch of the pulmonary artery and the incision closed by lateral application of the special Trendelenburg clamp. The heart now began to beat more strongly and normal respiration was resumed. The pulmonary artery was repaired by suture; it proved impossible to close the parietal pericardium, but the superficial wound was repaired in the usual way. Towards the end of the operation the patient began to regain consciousness. For some days there was evidence of a disordered cardiac action, but after a course of rest and digitalis he left hospital cured.

<sup>1</sup> Valdoni, P.: Policlinico, May 18th, 1936, p. 911.

Wustmann and Hallervorden<sup>2</sup> have recorded the experience of the Frey clinic with the operative treatment of pulmonary embolism during the last two years. In all, 6 cases were subjected to operation; it is worth noting that the diagnosis was correct in each case and that in one there had been a smaller embolus two days before the fatal attack. In 3 patients death had come very suddenly, and when the heart was exposed at operation all signs of cardiac action had ceased and attempts at revival proved fruitless. The 3 remaining patients, although the clot was removed and effective cardiac action restored, survived only for a limited period—36 hours was the maximum. In all 3 cases death resulted from failure of the central nervous system, which had suffered irreparable damage during the initial period of heart failure.

Of recent years some authorities have doubted the practical value of the Trendelenburg operation. There can indeed be few operations so open to reasoned and informed criticism. At the same time it should be remembered that the victim of a massive pulmonary embolism dies of heart failure, and, although only 11 patients have permanently survived after operation, in at least another 35 normal cardiovascular action has been restored. Success demands experience both in diagnosis and in operative technique, but given these it seems imperative that the operation should be attempted, for apart from its value to the individual patient each success is important as a demonstration of the possibilities latent in modern surgical technique.

#### HISTIDINE TREATMENT OF PEPTIC ULCER

THE experimental basis for the use of histidine in the treatment of peptic ulcer has been subjected to severe criticism. No one studying the original observations upon dogs could feel convinced that any amino-acid deficiency was actually present in these animals or that the ulcers produced were strictly comparable to the chronic ulcer of man. Hence the widespread employment of histidine has been chiefly founded, empirically, on its apparent power to relieve the symptoms of ulcer in man, as in the short series of cases reported by Dr. Gardiner on p. 1352 of our present issue. But now from America come reports of similar symptomatic improvement from the intramuscular injection of distilled water or saline. Sandweiss<sup>3</sup> giving a daily injection of 5 c.cm. of distilled water to 20 ulcer patients found that 12 became symptom-free (5 after the first injection) while corresponding improvement was noted in only about the same proportion of patients treated with histidine (22 out of 40). Martin<sup>4</sup> observed relief of symptoms in 3 out of 6 patients following saline injections. Even so few observations as these suggest that histidine can hardly exercise a specific effect upon the healing of peptic ulcer, and numerous other non-specific injections have for many years found warm supporters, Sandweiss mentioning as many as eleven. Nevertheless accounts of its beneficial effects continue to appear, and Martin and Sandweiss's papers allow some critical comparison of this method of treatment with the more orthodox diet and alkali régime to be made. On the whole their reports are not favourable. Thus Sandweiss, out of 67 patients, found that of those treated with histidine, 85 per cent. had recurrence of symptoms

<sup>2</sup> Wustmann, O., and Hallervorden, J.: *Deut. Zeits. f. Chir.*, 1935, cexlv., 472.

<sup>3</sup> Sandweiss, D. J.: *Jour. Amer. Med. Assoc.*, April 25th, 1936, p. 1452.

<sup>4</sup> Martin, K. A.: *Ibid.*, p. 1468.

within six months as against only 31 per cent. of those treated by diet and alkali. In the two treatments about the same proportion became symptom-free, but of 24 patients checked by radiography or operation after histidine treatment, not one showed disappearance of the ulcer deformity. Martin's results in two comparable series of ulcer patients are similar; thus of 32 patients watched for ten months after histidine treatment only 13 have had no recurrence, whilst 16 out of 40 patients treated by diet and alkali are still well after this time, 24 having had relapses. Acting largely upon Dr. Martin's report the Council on Pharmacy and Chemistry of the American Medical Association have postponed further consideration of the use of histidine "until adequate clinical evidence of its therapeutic value" is forthcoming. Their caution emphasises again the need for care in using histidine treatment at the expense of dietary principles that have had longer trial.

### OPERATION FOR AURAL VERTIGO

AURAL vertigo is fairly common, but its severity is extremely variable. In many patients the symptoms are not so serious as to interfere greatly with their mode of life and work; these will usually make satisfactory progress with reassurance combined with an occasional course of a mild sedative drug, and there is often a tendency towards spontaneous cure. But some, a minority, lose their morale and are prevented from working by the frequency and severity of the attacks. In such cases operation is justifiable, and intracranial section of the auditory nerve has been shown to lead to dramatic cessation of the vertigo. There is usually severe deafness on the side involved, so that the total loss of hearing which follows the operation is of little moment. In some patients, however, who suffer from Ménière's syndrome, there is no great deafness, and it is highly desirable to save the hearing. This is possible if the vestibular portion of the nerve is divided without damage to the cochlear fibres. Dr. K. G. McKenzie,<sup>1</sup> of Toronto, has now performed this operation on 12 patients; of these, 7 had such poor hearing on the affected side that it was of little importance to save the cochlear nerve, but in all of these such hearing as they had was not further impaired. Of the 5 with useful hearing, in 1 the cochlear nerve was unintentionally cut, and 1 died of wound infection which caused an extradural abscess compressing the cerebellum. In the remaining 3 cases the hearing was not made worse, and all 11 patients lost their attacks of vertigo. A little unsteadiness remained for a few weeks or months but this gradually disappeared, and the only relic of vertigo is a slight tendency, in a few cases, to fall towards the affected side when turning suddenly in the dark.

At operation, access is obtained through an opening over the cerebellum, made as high and as lateral as the lateral sinus and mastoid cells permit. The vestibular portion of the nerve lies above and behind the cochlear portion; a groove or line of cleavage is sometimes seen between the two, but there is no real septum. The vestibular fibres are larger and have a thicker medullary sheath than the cochlear fibres. McKenzie's method is to make a short incision into the centre of the nerve parallel to its fibres, to insert a blunt right-angled hook over the postero-superior half of the nerve which contains the vestibular fibres, and to cut down on to the hook with a

sharp knife. It is not necessary to isolate the facial nerve, which lies in front separated from the auditory nerve by the pars intermedia of Wrisberg, and in this respect the operation is easier than when the cochlear nerve, which lies closer to the facial, is divided as well. A further advantage is that it is usually possible to avoid a small artery which runs in the centre of the nerve, but which he has found to lie on the cochlear side of the longitudinal incision.

These cases of aural vertigo nearly always have unilateral deafness and tinnitus, or at least these symptoms are much more severe in one ear, so that there is no difficulty in deciding on which side to operate; in one of McKenzie's cases there was some doubt, but there has been no recurrence of the attacks after operation of the deaf ear. He has found the caloric response of no value as a lateralising sign; the reactions as a whole had a tendency to be sub-normal without definite difference between the two sides. The nystagmus, also, had no value in this respect, being sometimes to the sound, and sometimes to the affected side, while in one patient it varied in different attacks. Again, the direction in which objects appear to move was of no assistance; 7 of the 12 patients were unable to give any definite direction; in 3 the objects moved towards, and in 2 away from the side of the lesion. Most preferred to lie on the back, one would only lie on the affected ear, and one was equally emphatic that he could lie only on the good ear. The effect of vestibular section on tinnitus is interesting. Of the 12 patients, 1 died, 1 had a section of the entire nerve, and 1 had no tinnitus; of the remaining 9, 2 had complete cessation, 2 were unchanged, and in 5 tinnitus has much diminished. It may therefore be expected that this symptom will be alleviated after division of the vestibular nerve alone; it is noteworthy that a mild tinnitus has been found to persist in about half the cases treated by complete section of the auditory nerve. As would be expected, caloric response is usually absent after operation, but 2 of McKenzie's patients showed a slight reaction from the vertical canals, which suggests that it is not necessary to cut all the fibres of the vestibular nerve in order to cure the vertigo.

The operation described seems no more difficult than complete section of the auditory nerve, and apparently has several advantages over it, especially when useful hearing remains in the affected ear.

### THE B.P. ADDENDUM

ON the first of this month the eleventh edition of the Pharmacopœia of the U.S.A. came into force. It has been the aim of the British Pharmacopœia Commission to come into line as closely as may be with American practice in the draft for the B.P. Addendum which is now so far advanced that copies may be available in September next, although publication cannot take place before the following December. We have already enumerated<sup>1</sup> some of the more important drugs which are to be described in this Addendum, including five new antitoxic sera. At the meeting of the General Medical Council last month Sir Henry Dale presented a report from the Pharmacopœia Committee calling attention to the prolonged consideration which has been given to the inclusion of the newer remedies which are coming into general use. It was then agreed to reappoint in September, when their present term of office expires, the present eight members of the Commission and to reinforce its special knowledge of clinical thera-

<sup>1</sup> *Canad. Med. Assoc. Jour.*, April, 1936, p. 369.

<sup>2</sup> *THE LANCET*, April 4th, p. 793.

peutics and pharmaceutical chemistry by the addition of Prof. F. R. Fraser who served on the committee from 1928 to 1933 and of Mr. W. H. Linnell, Ph.D., director of the Pharmaceutical Society's chemical research laboratory. It is satisfactory to know that the Addendum is to appear this year. The prodigious gap between the issues of the Pharmacopœia of 1914 and 1932 led to some natural despondency about the way in which the G.M.C. was keeping the official drug list in touch with modern therapeutics, however closely it was observing its statutory duties. We may hope that the interval between successive pharmacopœias will never be more than ten years again.

### THE PRINCES IN THE TOWER

Prof. William Wright's Cavendish lecture drew a large audience to the West London Medico-Chirurgical Society on June 4th, and he kept them fascinated by his modern commentary on the tragic story of the Princes in the Tower. The two boys, Edward and Richard, were the sons of Edward IV., and after their father's death the elder (Edward V.) was seized by his uncle Gloucester (afterwards Richard III.), who lodged him in the Tower, ostensibly to be in readiness for his coronation. On June 16th, 1483, he was joined by his brother, the Duke of York, and neither was ever seen again outside the walls. A detailed account of their murder by Gloucester's agents, probably in August or September, 1483, was given by Sir Thomas More in his "Historie of Kyng Rycharde the Thirde" (1513), but its authenticity has been questioned and some have held that Henry VII. killed them after he came to the throne in 1485. A potential source of evidence was the group of bones discovered at the base of the White Tower in 1674 and buried in Westminster Abbey by Charles II.'s orders. These were examined by Prof. Wright in 1933 and he found that they were the bones of two children differing by two or three years in age as judged by the length of their bones. An attempt to fix the age of the elder more precisely was rewarded by the discovery of the second cervical vertebra: the tip of its odontoid process had not united, and from this it could be deduced that the child was less than 13 years old. Assuming its owner to be Edward V., who was born on Nov. 2nd, 1470, he must have died long before Henry VII.'s accession, and there is reason to accept Sir Thomas More's story that they were murdered at the ages of 12 and 10. That the bones are really those of the princes is supported by the situation in which they were discovered and by anatomical signs of consanguinity. These are (1) wormian bones of unusual size and almost identical shape in the lambdoid sutures of both crania, and (2) absence of the upper second premolars in the elder coupled with absence of the lower second deciduous molar in the younger. Absence of deciduous molars is exceedingly rare, and the findings suggest not only tooth-suppression in both children but tooth-suppression in the same regional plane.<sup>1</sup> A remarkable feature of the elder boy's facial skeleton was an extensive reddish-brown stain reaching from just below the orbits to the angles of the lower jaw—a finding consistent with death by suffocation. In Prof. Wright's opinion the evidence that the bones are those of the princes is as conclusive as could be desired and definitely more conclusive than could reasonably have been expected.

<sup>1</sup> The investigations are fully described by Mr. Lawrence Tanner and Prof. Wright in "Recent Investigations regarding the Fate of the Princes in the Tower," communicated to the Society of Antiquaries. *Archæologia*, vol. lxxxiv.

And if Sir Thomas More's story contains coincidences these are the coincidences of real life, not those of invention.

### DR. HURTLEY

MANY generations of students at St. Bartholomew's Hospital will learn with regret of the death of Mr. William Holdsworth Hurlley, D.Sc. He first came to the hospital in 1899 as assistant to Dr. Chattaway whom he succeeded as lecturer in 1906, becoming a reader in chemistry at London University in 1922. Hurlley was a teacher who took trouble in the preparation of his lectures and demonstrations with the result that they always fulfilled their purpose. He was a good organic chemist, and although his teaching hours were long he found time for research work, collaborating with the late Sir Archibald Garrod in papers on alkaptonuria and cystinuria. He did original work on the acetone bodies and bile acids, and his study of the estimation of iodine in the blood led to the development of a standard method. At the hospital Dr. Hurlley was beloved by all who came in contact with his courtesy, modesty, and honesty. Of a retiring disposition he rarely emerged from his laboratory, but he would spare unlimited time to anyone who sought his advice on chemical problems. During the last five years, although over the normal retiring age of 65, he reorganised the teaching of biochemistry for the second- and third-year students, and carried through all the arrangements for the new chemical laboratories at Charterhouse-square. He was due to retire at the end of the present session, but did not recover from an attack of pleurisy and bronchitis which befell him in April. He died in the hospital on June 2nd.

### THE DANGERS OF THE FEATHER PILLOW

THE risk of a baby suffocating itself in a soft pillow is often considered negligible, and many medical practitioners doubt the possibility of such an accident until they come across an actual example. A tragic case of this sort has lately been the subject of comment by the coroner for East Sussex. A baby of 3½ months was left in its perambulator and found dead with its head buried in a feather pillow. The coroner remarked on the danger of such pillows and also upon the amazing fact that a strong infant may fail to make the necessary movements to free its face. Yet books on the care of infants hardly mention pillows at all and in consulting the standard manuals for mothers one finds no warning in strong enough terms. Unfortunately it is seldom possible for newspaper reports to be certain about all the relevant facts of the case. In the first place the mentality of the infant is seldom mentioned, possibly in order to spare the parents' feelings; yet it is highly important. Medical men who would admit the possibility of self-suffocation by a mentally deficient child hesitate to believe that a normal strong baby can fail to save itself. If soft pillows are dangerous to normal infants, what about blankets and eiderdowns? It might be argued that it is hardly ever safe to leave a baby alone. On the other hand if the risk is only serious when the infant is mentally defective the responsibility of parents or nurses of normal babies is greatly reduced. Another point concerns the possibility of such deaths occurring among those who were formerly supposed to have "status lymphaticus." Certainly this term has been used at some of the inquests, and though it is no longer admissible we may still conceive that some

children are peculiarly susceptible to sudden death from trivial causes. It is interesting that the risk arising from feather pillows should be minimised while those of overlying are generally admitted: and it seems that overlaid babies often die without much protest. The coroner for East Sussex requested the practitioner who was called to the recent case to tell all his patients not to use feather pillows for young children. Substitutes include pillows filled with chaff or hard vegetable flock, or even no pillow at all. Clearly in the present state of knowledge the feather pillow should be barred; but, as already suggested, this knowledge may well be incomplete. It is hard to believe that a normally strong infant relinquishes its hold on life without some effort.

#### ARTIFICIAL RADIO-ACTIVITY

FRESH from her appointment as under-secretary for scientific research in the new French Ministry, Mme. Joliot-Curie last week gave an address in London on the synthesis of new radio-active elements. The occasion was a meeting at the Wigmore Hall of the Medical Association of the International Clinic at which Lord Lytton presided. Mme. Joliot-Curie began by resuming the results of recent research in atomic physics, which she described as an explosion of new knowledge, international in range. The term explosion may be applied also to the method employed, which is bombardment of normal matter by projectiles of atomic size. The explosion of the naturally occurring radio-active elements has supplied us with alpha and beta rays, and we have long been aware of the fast-moving electron of the discharge tube; but recent investigations have given us the neutron, the hydrogen nucleus or proton, and the positive electron. With these weapons the physicist has attacked the elements, subjecting each in turn to an atomic barrage, knowing that if enough projectiles are fired some hits must be scored. The results of such hits on the nucleus were at first found to be a disruption of the atom struck, with the production of other known elements; later, evidence was forthcoming in some experiments of unstable forms or isotopes of elements, which were of themselves radio-active. When the source of bombardment was removed in these cases, the activity of the treated material continued for a period in diminishing intensity according to the well-known law governing natural radio-activity. These new elements of laboratory manufacture are of such short life that they are unlikely to be found in nature. They have been identified by the use of a Wilson cloud chamber in which their ionising paths are photographed by the tracks of condensed water vapour. The quantities produced are small, so small indeed as to elude the tests of chemistry, but owing to rapid decay the intensity of radiation is by no means negligible. Mme. Joliot-Curie considered the possible medical application of these elements. They are, as she pointed out, of lower atomic weight than those occurring in nature; hence when introduced into the body by injection or absorption they will find their way by the normal chemical reactions to certain organs. Radio-activity may thus be applied selectively, and with agents whose activity is temporary. In support of these speculations she showed some photographs of sections of organs in which radio-activity had been naturally concentrated by biochemical action, the concentration being sufficient to record itself on a photographic plate. Mme. Joliot-Curie concluded by emphasising the contribution of many countries to the growing knowledge of the ultimate structure

of matter—a knowledge to which her illustrious mother's discovery provided the key. We may hope that the engrossing work of a new Cabinet department will not divert her energies too far from her own fruitful inquiries.

#### THE BASIS OF TROPICAL MEDICINE

IN delivering the Stephen Paget lecture of the Research Defence Society last Wednesday Sir Malcolm Watson began by speaking of the way in which Paget gave freely of his time and his money so that research for the cure and prevention of disease might proceed without obstruction. To illustrate the astonishing value of such research in saving life and reducing misery he recounted some of the achievements of tropical medicine, and described in vivid phrases the discoveries of Manson, Ross, and Walter Reed. To Manson he applied Stevenson's words: "Study and experiment, to some rare natures, is the unbroken pastime of a life," and he showed how tremendous an influence such an "enviable nature" may have upon his fellows and their environment. Ross carried on the torch of investigation, and "already we can claim to have saved a million lives and an incalculable amount of sickness" as a direct result of the researches of these two men. In Cuba Reed and his collaborators combined patient inquiry with unforgettable heroism; and some of them lived to see great results from their final proof that yellow fever is carried by a mosquito. To-day their work continues and experimental research on animals provides hope that we shall be able to prevent the spread of this disease into regions like Asia, where it is otherwise capable of spreading through dense populations "as if a fire ran through the prairies."

ON Monday next Prof. J. H. Stokes, of Philadelphia, will deliver the Prosser White oration of the St. John's Hospital Dermatological Society. His subject is the Control of Syphilis, and the meeting will be at 1, Wimpole-street, W., at 5 p.m.

**ROYAL MEDICAL BENEVOLENT FUND.**—At a recent meeting of the committee of this fund 19 new applicants were assisted and 34 grants were renewed to beneficiaries. In all £1346 was voted. The following particulars of a few cases helped indicate the kind of work undertaken:—

Widow, aged 40, of M.B. who died last year aged 39. Her husband had worked as a medical missionary in North China, and she was left with a capital of only £1300, and three children to educate and maintain. Fund voted £26 plus a special gift of £10. The Ladies' Guild will assist with education of children.

Daughter, aged 61, of M.R.C.S. who died in 1927. Her father practised for some 30 years and was much loved by the poor. She has a few pounds only of her own, and makes up her income by needlework; but of late her health has been giving way and she can no longer work eight hours a day at her needle which she has to do if she is to earn enough to keep herself alive. Fund voted £26.

Widow, aged 63, of M.D. who died in 1927. Since her husband's death the widow has endeavoured to support herself. Recently she has held housekeeper's positions, which now through ill-health she finds difficult to get and to hold, age and ill-health being against her. Income £51 per annum. Fund voted £26.

This is the centenary of the fund and a special appeal is being made for new subscribers to raise the annual income, by subscriptions and donations, to £20,000. From the present income of £14,000 allowances of £40 and £26 are made to medical practitioners and their dependants respectively. An appeal is also being made this year for special donations to create a fund from which larger grants can be voted to very urgent and distressing cases, and which may be used to help with the training of the widows and orphan sons and daughters of medical practitioners to enable them to be self-supporting. Cheques should be made payable to the hon. treasurer of the Fund, 11, Chandos-street, Cavendish-square, W.1.

## PROGNOSIS

*A Series of Signed Articles contributed by invitation*

### CIV.—PROGNOSIS OF HAND INFECTIONS

HAND infections fall into many different types, the prognosis of each of which must be considered separately. In the first place there are *variations in bacteriology*, the severity of the infection depending upon the organism. Infection of the hand of the surgeon or nurse from a prick during an operation or dressing on a patient suffering from streptococcal or pneumococcal septicæmia may be followed by grave illness and even death. On the other hand, infections with the staphylococcus are not usually dangerous to life.

In the second place there are *variations in the anatomical type of infection* which greatly modify the prognosis, and these will be discussed later. Similarly, *variations in treatment* will have a profound effect upon the course of the infection, and these will have to be considered seriatim. Nor is it out of place to consider prophylaxis in its relation to these infections.

#### Prophylaxis

Between 5 and 25 per cent. of all disabilities are due to infections of the hand, the proportion varying with the trade of the workman. Removal from one factory of minor causes of injuries (broken tins, baskets, nails, pins) reduced the incidence of injury to less than one-seventh of its previous figure. In another instance the use of tincture of iodine after all injuries reduced the incidence of infections by 38 per cent., and diminished the severity of those occurring. Hospitalisation of all cases were this possible would doubtless still further reduce morbidity. Industrial organisations should be urged to provide instruction and facilities for treatment.

#### Anatomical Types of Infection

The principal anatomical types of infections will now be considered.

##### SUBCUTICULAR WHITLOWS

Subcuticular whitlows are little more than infected blisters, and have the appearance of bullæ containing pus. The treatment of the ordinary case is to remove the raised cutis aseptically and apply spirit to the exposed area. During the first few days the edge may continue to "grow," but with further treatment the condition rapidly disappears within 5-7 days. A blister at the base of the finger which becomes infected is more serious, for, the skin being thick, there is a tendency for the pus to track into the subcutaneous tissues forming a "collar-stud" abscess and a whitlow of the second variety.

##### SUBCUTANEOUS WHITLOWS

These form the biggest group of hand infections. Owing to the density of the fibrous tissue in the pulp of the fingers, the fat is disposed in loculi, which upon infection become extremely tense. The pus ruptures from one loculus to the next, the condition spreading slowly and insidiously, until a considerable portion of the finger is involved. The danger of an expectant policy at this stage cannot be over-emphasised, and continued hot dressings merely serve to conceal the progress of the disease. If the infection begins in the distal phalanx the tension developed is sufficient to obstruct the blood-supply to the bone at an early date, leading to

necrosis followed by sequestrum formation, the basal epiphysis being spared longer than the rest of the bone. If the infection involves the proximal parts of the finger, pus may travel via the lumbrical muscle into the thenar or middle palmar space, leading to further complications and corresponding delay in recovery. Furthermore, a neglected subcutaneous whitlow may lead to infection of the tendon sheath, which is extremely grave, or to direct destruction of bone, which also prolongs and increases the incapacity.

For these reasons it is clear that the prognosis of a subcutaneous whitlow is directly related to the stage at which and the method by which the finger is treated. As soon as the condition is diagnosed on the five cardinal signs of suppuration, and long before fluctuation is evident, a free incision must be made under regional or general anæsthesia, with a tourniquet round the arm or the base of the finger. The incision should be placed laterally, and every infected loculus must be drained; horseshoe-shaped incisions over the tip should be avoided as the resulting scar is often unsatisfactory. Twenty-one days should see the finger practically healed. Delay in resolution means that the incision was not adequate, or that some complication has arisen. Palmar and thenar space infections resolve rapidly after appropriate incisions; tendon sheath and bone infections are discussed below.

##### THECAL WHITLOWS (TENOSYNOVITIS)

These may follow direct infection of the sheath as from a needle prick, or be the sequel to a neglected subcutaneous infection. In the thumb tendon, the infection rapidly passes up to the wrist region, and may then pass down the little finger or vice versa. In the index, middle, or ring fingers the infection may rupture into the thenar or middle palmar space. Profound septicæmia is also to be feared in tendon sheath infections, with all its dangers. Apart from these complications, the tendon itself tends to undergo necrosis at an early date, and later sloughs out completely, leading to complete loss of function of the finger. Bone involvement is also to be feared in neglected cases.

Long incisions along the line of the tendon have been advocated, but in my experience usually lead to prolapse and loss of the tendon, with a functionless finger which too often has to be amputated. Short lateral incisions draining the more dilated parts of the sheath opposite the flexures, with particular attention to the proximal cul-de-sac, may save the finger. In thumb and little finger infections, the common flexor sheath has to be drained above the wrist by lateral and medial incisions. A perfect functional result is sometimes seen, though this is very rare in spite of careful post-operative re-educative exercises. Much more frequently a stiff and possibly deformed finger is the outcome, if indeed it is saved at all. The period of incapacity may be from two weeks to several months, and permanent incapacity is not unlikely.

##### SUBPERIOSTEAL WHITLOWS (OSTEOMYELITIS)

These may be extensions from any of the foregoing varieties, the result of a compound fracture, or in rare cases, of a blood-stream infection. The disease itself does not produce a high state of toxæmia as is common with osteomyelitis of larger bones, and is

not in itself dangerous to life. Except in metastatic infections and in rare primary infections of bone immediate operation is not called for, assuming that drainage has already been provided. The infection is of a chronic order and one has to wait for the natural processes of sequestrum formation, which may take many months to complete. Nothing is gained by premature interference.

Deformity is to be expected from loss of bone, although new bone may form to an amazing extent, while in cases where the joint surfaces have been involved bony ankylosis is usual. A stiff straight finger is a nuisance to a working man, who may beg for amputation. If the hand has been maintained

in the "position of function," wrist dorsiflexed, fingers partly flexed, the deformity is less noticeable and less inconvenient, for a considerable amount of movement is usually preserved at the metacarpophalangeal joints. Suppurative arthritis of the proximal interphalangeal joint is a definite indication for early amputation, for otherwise after many weeks of suppuration a stiff finger will be the inevitable result. Most patients prefer to accept a reduction in morbidity at the expense of the loss of the digit.

NILS ECKHOFF, M.S., F.R.C.S.,  
Assistant Surgeon, Guy's Hospital.

(To be continued)

## SPECIAL ARTICLES

### THE FATE OF A POPULATION OF WOMEN MEDICAL STUDENTS

By M. H. KETTLE, M.R.C.S. Eng.

BETWEEN the years 1916 and 1924 inclusive St. Mary's Hospital Medical School was open to women as well as to men students. Their admission arose from the circumstance that during the war the London School of Medicine for Women (L.S.M.W.) sought relief from the congestion of clinical students at the Royal Free Hospital, while St. Mary's, in common with other London medical schools, was suffering financially and otherwise from their lack. Later, women were accepted, not only for hospital training, but for the whole medical course at St. Mary's until in 1924 for reasons which, it was officially stated, had nothing to do with the efficiency, industry, or conduct of the women students, the decision was taken to admit no more of them.

Altogether, 255 women entered St. Mary's during the nine years.<sup>1</sup> Of these, 222 came for the clinical course only, 210 from the L.S.M.W., and 12 from elsewhere (e.g., Oxford or Cambridge); 2 did some pre-clinical work at St. Mary's, and 31 entered St. Mary's for the whole medical course. The students from the L.S.M.W. were in no way selected; they were asked to indicate which of the two hospitals open to them they would prefer to attend, and as far as possible their wishes were met.<sup>2</sup> It seemed likely that an analysis of the subsequent careers of those women who qualified from St. Mary's and of their distribution through various branches of the profession would be of interest, since they provide a complete though small population. They may or may not be a fair sample of all women who entered the profession during the same period, but there is no reason to regard them as atypical. The tables set out below were compiled from the answers to a questionnaire issued on behalf of the St. Mary's Hospital Medical Women's Association in May, 1934, to all the qualified women who could be traced. They were asked to state (a) name and address, (b) qualifications and diplomas, (c) jobs done since qualifying, (d) present professional work, if any, and (e) whether married; they were also (f) given an opportunity, which 88 of them took, to comment on

women's work in medicine. Question (e) was later supplemented by a query, addressed to those known to be married, about children, in order to ascertain, if possible, to what extent a decision to drop professional work was influenced by the ties of a family.

#### Proportion of Women Qualified

Interest centres first on the proportion of the 255 entrants who achieved qualification. It emerged (Tables I.A and I.B) that 230 (90.2 per cent.) of the

TABLE I.A.—Proportion Qualified

	Alive.	Dead.	Total.
Number of women—			
Qualified .. ..	220	10	230 (90.2%)
Unqualified .. ..	21*	4	25 (9.8%)
Number who attended hospital .. ..	241	14	255 (100.0%)

\* 12 of these are known to be married.

TABLE I.B.—Sources of Information

Unqualified women—			
Records of St. Mary's Hospital Medical School and private information .. ..	..	..	25
Qualified women—			
Replies to questionnaire .. ..	..	..	203
Books of reference, including past and present medical registers, medical directories, and hospital calendars .. ..	..	..	27 = 255

entrants became doctors. This is a creditable percentage, but it must be remembered that most of them had already passed two out of the three professional examinations on admission to St. Mary's.

Of the 25 (9.8 per cent.) who did not qualify, 4 died as students; of the rest, assumed to be alive, 12 are known to be married, some of them giving marriage as a reason for withdrawal. Most of the withdrawals seem to have been during the first or second clinical years.

#### Qualifications Obtained.—Higher Degrees and Diplomas

Table II.A shows that while 212 women took the Conjoint Board diploma, 77, or more than a third of this number, took a degree also; 15 women took a degree only; 2 took the L.S.A. only; and 1 the L.D.S. only.

Table II.B shows higher degrees and diplomas. Higher degrees in arts and science were ignored because usually there was no indication whether these had been obtained before medicine was even contemplated as a career, but at least one

<sup>1</sup> Three of them, previously enrolled, did not actually begin work until 1925.

<sup>2</sup> Of the first batch to enter St. Mary's, in May, 1916, 4 had already spent one of their clinical years at the Royal Free Hospital and 8 had recently passed the second professional examination. Subsequent batches of students had had no previous hospital experience.

D.Sc. and one M.Sc. can legitimately be claimed and one general practitioner has become a barrister-at-law. One M.R.C.P. was awarded on published research work, and one F.R.C.S. Eng. is held by a woman who had already gained the university medal in her London M.D. The M.C.O.G. had only recently been established at the time the questionnaire was issued, which may account for the fact that only one holds this diploma.

TABLE II.A.—Qualifications Obtained

Qualification.	No. and per cent.
L.D.S. only .. .. .	1 (0.4)
L.S.A. only .. .. .	2 (0.9)
L.R.C.P., M.R.C.S. (1 with L.D.S.) ..	135 (58.7)
M.B., B.S.* .. .. .	15 (6.5)
L.R.C.P., M.R.C.S.; M.B., B.S.* ..	77 (33.5)
	230 (100.0)

TABLE II.B.—Higher Degrees and Diplomas

	No. and per cent.		No. and per cent.
M.D.* .. .. .	21 (9.1)	D.T.M. & H.* ..	7 (3.1)
M.R.C.P. .. .. .	3 (1.3)	D.P.M.* .. .. .	6 (2.6)
M.S. .. .. .	1 (0.4)	D.M.R.E. ....	3 (1.3)
F.R.C.S. (Eng. 5, Edin. 2) ..	7 (3.1)	D.O.M.S. ....	5 (2.2)
M.C.O.G. .. .. .	1 (0.4)	D.L.O. ....	1 (0.4)
D.P.H. .. .. .	26 (11.3)		81 (35.2)

\* For simplicity, all degrees are included as M.B., B.S., though a few women qualified from universities with a different designation—e.g., M.B., B.Chir. Similarly all diplomas of tropical medicine (i.e., D.T.M. Liverp.) are included as D.T.M. & H., and the category D.P.M. includes a diploma of psychology gained at Geneva. All but three of the M.D.'s are M.D. Lond.

How Many are Working ?

From Table III.A it is seen that of the 230 women who qualified 99 (43.0 per cent.) married and 127 (55.2 per cent.) remained single, the civil state of the

TABLE III.A.—Numbers Working

—	Work-ing.	Light work.	Not under-taking professional work at present.	No state-ment.	Dead.	Total.
Single.	111	1	7	1	7	127 (55.2%)
No statement re marriage.	2	..	..	2	..	4 (1.7%)
Married, with-out children.	19	3	8	1	..	31 (13.5%)
Married, with children.	26	10	19	2	..	57 (24.8%)
Married. No statement about children.	1	..	3	4	3	11 (4.8%)
—	159 (69.2%)	14 (6.1%)	37 (16.1%)	10 (4.3%)	10 (4.3%)	230 (100.0%)

TABLE III.B

—	Working.	Not undertaking professional work at present.	Total.
Single.	112 (94.1%)	7 (5.9%)	119 (100%)
Married, without children.	22 (73.3%)	8 (26.7%)	30 (100%)
Married, with children.	36 (65.4%)	19 (34.6%)	55 (100%)
—	170 (83.3%)	34 (16.7%)	204 (100%)

remaining 4 (1.8 per cent.) being unknown. Of the single women 111 are working, 1 is doing light work,

7 are for various reasons not undertaking professional work at present,<sup>3</sup> and 7 are dead. Of the 96 living married women 46 are working, 13 are doing light work, and 30 are not undertaking professional work at present. The present occupation of the remaining 7 is unknown.

The proportion of married women without children who continue professional work is greater than that of married women with children, but only slightly (Table III.A). This is shown more clearly in Table III.B, which is derived from Table III.A by excluding the qualified women who are dead (10) and those about whom no information is available in respect of either marriage, present work, or children (16). This leaves 204 women: 119 single, of whom 112 (94.1 per cent.) are working; 30 married without children, of whom 22 (73.3 per cent.) are working; and 55 with children, of whom 36 (65.4 per cent. are working.

No attempt has been made to estimate the fertility-rate, but excluding adopted (3) and step-children the number of children produced of whom records are available is 117.

Distribution Through the Profession

Table IV.A is an attempt to get a cross-section of the distribution of the qualified women in different branches of the profession at the time of the inquiry, without reference to posts previously held or to future

TABLE IV.A.—Showing Present (1934-35) Distribution of the 230 Qualified Women

	No. and per cent.
1. In general practice, at home or abroad ..	87 (37.8)
2. Specialists (consultant, academic, or research) ..	32 (13.9)
3. Full-time hospital posts (resident) .. .. .	11 (4.8)
4. Full-time public service and public health posts	12 (5.2)
5. Government service abroad (including W.M.S. of India) .. .. .	5 (2.2)
6. Mission service, at home or abroad .. .. .	8 (3.5)
7. Medical officer to commercial firm .. .. .	1 (0.4)
8. Dentists .. .. .	2 (0.9)
9. Light work (welfare clinics or other part-time work) .. .. .	14 (6.1)
10. Not undertaking professional work at present ..	37 (16.1)

12. Dead .. .. .	10 (4.3)
	230 (100.0)

prospects. No account was taken of the (very few) cases where a change was contemplated—e.g., from general practitioner to anaesthetist—or likely to be enforced—e.g., dismissal from a public health appointment on marriage. The group most affected by this rigid interpretation of the information provided is that of “not undertaking professional work at present.” Those whose part-time occupations may not depend directly on the possession of a medical qualification, such as lecturing on physiology or hygiene to school-children, welfare societies, or girls’ clubs, or dispensing, are categorised as “not undertaking professional work at present.” Women who say they do “occasional locums” for their husbands are also placed in this group, which, moreover, may be unduly swollen by the inclusion, besides those definitely on the retired list, of single women who are looking for a practice after several years abroad, such as a professor of medicine at the Lady Hardinge Medical College, India, recently retired; or are taking a long holiday, for example one who after five years as medical superintendent of a mental hospital is now breeding schnautzers in the Antipodes; and

<sup>3</sup> For explanation of the categories “light work” and “not undertaking professional work at present” see below.

of married women who propose to resume work when their children are older. That this may be no mere aspiration can be deduced from the fact that one who entered in 1917 and married in 1918 (4 children) resumed her studies after 10 years, qualified in 1933, and is now engaged on productive honorary research work.

1. *General practitioners.*—Unfortunately no inquiry was made whether a practitioner had acquired her practice by purchase or by putting up a plate, or was working as principal, partner, or assistant. Though several gave this information spontaneously, there are too many who did not particularise to make possible valid deductions from the replies. At least 12 are known to be in partnership with their husbands, 2 with their fathers, and 1 with a brother. From the comments in response to Question (f) it is clear that some firms of three or four women partners have been established; the acquisition of a new partner seems mostly to have been followed by a corresponding increase in the gross earnings.

*Practitioners with hospital appointments.*—Group 2 in Table IV.A was confined to those who, as far as could be ascertained, do no general practice. Many of those grouped as general practitioners in Group 1 who are attached to the honorary staff of their local hospitals in the capacity of physician, surgeon, psychiatrist, anaesthetist, and so forth, have acquired in varying degree a consultant status in the district. For example, one practitioner (F.R.C.S.Eng.) is attached to a general hospital as a surgeon; one spends half her time as assistant pathologist to a women's hospital; one holds the appointment of radium officer to a large general hospital; one is on the staff of a hospital for mental and nervous disorders and her practice is becoming specialised in this direction.

TABLE IV.B.—*Distribution of General Practitioners*

G.P.'s in provinces.	G.P.'s in London.	G.P.'s abroad.	G.P.'s now in practice.
57 (65.5%)	25 (28.7%)	5 (5.8%)	87* (100%)

\* Of these, 27 are on the staff of their local hospital, in an honorary capacity or with an honorarium.

Table IV.B shows the number of general practitioners working in London (25), the provinces (57), and abroad (5). Of the total number of general practitioners now working, 27 (nearly one-third) are on the staffs of hospitals.

2. *Specialists. (consultant, academic, and research).*—Of the specialists enumerated in Table IV.C many are on the honorary staff of more than one hospital, some of the posts not having previously

TABLE IV.C.—*Specialists (Consultant, Academic, or Research)*

Physician .. .. .	1	Radiologist .. .. .	1
Surgeon .. .. .	2	Physiologist .. .. .	2
Gynaecologist .. .. .	1	Pathologist .. .. .	4
Anaesthetist .. .. .	5	Research worker .. .. .	4
Physiotherapist .. .. .	2	Medical journalist .. .. .	2

Psychotherapist .. .. .	4		32

been filled by a woman—e.g., that of ophthalmic surgeon to a London teaching hospital and of surgeon to the premier British ophthalmic hospital. University posts held range from teacher (2), demonstrator (2), lecturer (2) to reader (1). These do not include a lectureship in physiology at a physical training

college or one in hygiene at a provincial university (which latter is held by a general practitioner). Of the research workers one is on the permanent staff of the Medical Research Council and is the author of important monographs. At least two others in this group of specialists have published successful books and original contributions of permanent value have been made by several of the women to special and general medical journals, one of which has a St. Mary's woman as an assistant editor. Of the two general surgeons one has a special interest in orthopaedics; the other has won distinction not only in professional but also in public life, being a prominent member of the L.C.C.

3. *Full-time hospital posts (resident).*—The list of specialists detailed in Table IV.C is perhaps improperly diminished by the exclusion of those who hold, or held at the time of the inquiry, responsible resident appointments. These 11 women include, for example, a resident physician at a large municipal hospital in the provinces; a resident medical officer at a mental hospital; and a resident medical officer at a private hospital for surgical tuberculosis.

4. *Full-time public service and public health posts.*—In this category of 12 women are grouped, besides assistant medical officers of health and school medical officers, two important civil servants—i.e., a medical inspector of factories under the Home Office (who has been allowed to keep her appointment after marriage) and a medical officer to Holloway Prison.

5–12. These categories in Table IV.A are self-explanatory. One of the five in Group 5 is the second St. Mary's woman to be appointed professor of medicine at the Lady Hardinge College, India.

### Post-graduate Experience and Previous Appointments

The cross-section of the distribution of the qualified women in 1934–35 set out in Table IV. takes no account of posts held or work done before that date, or of the ways in which the experience was gained which enabled the present post or success in general practice to be obtained.

TABLE V.A.—*Resident Posts Previously Held (H.P., H.S., &c.)*

St. Mary's.	Elsewhere.	Not known to have held a resident post.	Total.
94 (40.9%)	51 (22.2%)	85 (36.9%)	230 (100%)

TABLE V.B.—*Resident Posts Held by G.P.'s*

Those who had held resident post.	Those who had not.	G.P.'s (past and present).
73 (66.4%)	37 (33.6%)	110 (100%)

TABLE V.C.—*Total Number of Resident Posts Held*

St. Mary's.	Elsewhere.	Total.	Number of women who have held them.	Average number of posts held by each woman.
151	190	341	145	2.35

*Resident posts.*—In this connexion it is of interest to see (Table V.A) that of the 230 qualified women as many as 145 (63.1 per cent.) held one or

more resident posts before engaging in the branch of medicine that was later to absorb them. Of these 94 obtained posts at St. Mary's (and often elsewhere as well) and 51 obtained posts as residents only at other hospitals. Of the 110 women who have been engaged in general practice 73 had previously held resident posts in hospitals (Table V.B). Few of the 145 women who held resident appointments were content to apply for one only; some held as many as five or six in succession, not counting of course in this category the more permanent senior resident posts in general mental or special hospitals now held by 11 women (see Table IV.A Group 3). The average number of resident posts held by each of the 145 women works out to 2.35 (Table V.C).

*Other "learning" posts.*—At least 6 of the women have held one of the post-graduate research studentships available in the various departments of the Pathological Institute at St. Mary's, 8 have held registrarships (one at St. Mary's) and of course a very large number have gained experience as clinical assistants. Many still work at hospitals in this capacity while engaged in practice. The general impression given by study of the replies to the questionnaire is that whatever branch of work has been adopted considerable trouble has been taken to ensure adequate equipment for the responsibilities it entails.

#### Comments Made on Women's Work in Medicine

Eighty-eight of the women responded to the question "Would you care to make any comments on women's work in medicine, including income prospects?" The most striking feature of the comments is the emphasis laid on the scope for women in general practice, and this did not come only from those who were themselves doing this work. Several note that prejudice against women practitioners is fast disappearing and remark upon the friendly and helpful attitude of male colleagues. General practice is held on all sides to offer an interesting if strenuous life; but there are warnings against its adoption by those who are not physically strong, or on whom continuous domestic demands are likely to be made. One says: "The great mistake that many women G.P.'s commit is to make medicine a secondary interest to running a husband and family, or running clinics and school inspections."

Town practice is regarded as more suited to women than country practice, and some comment on the success which is likely to attend a man and woman practising together. "In my one case," says a partner in such a practice, "the income is difficult to judge, as the N.H.I. and other club cheques are paid jointly, but my private receipts often equal or exceed my husband's."

The financial returns from general practice appear to be satisfactory on the whole. Several who bought small nuclei, or put up a plate, record substantial annual increases in income, and others who bought established practices have taken in partners as the work has developed after a preliminary drop. The general impression is that it takes about five years to establish a practice as a sound profit-making concern, and that during these years a good deal of unpaid work will have to be done; an income derived from other sources is therefore essential, or some capital to be used as income during this period.

\* Of these 87 are still so engaged (see Table IV. A; the rest have either specialised, retired temporarily or permanently, or are dead.

Some women note that working-class patients go to women more readily than do well-to-do ones; others record a contrary experience. One or two of those in consulting practice appear to have prospered exceedingly, but for the most part consultants and specialists have said little about the financial aspect of their work. The tendency for increasing numbers of women to specialise in gynaecology was deplored by several observers, whose remarks must be taken to apply to women in general, since it is noteworthy that only one St. Mary's woman is a specialist in gynaecology in the sense that she does no general practice at all. It is a matter of comment that women practitioners tend to attract gynaecological and pædiatric cases, and that specialisation in these branches is often developed from and associated with a general practice. Some emphasise the need for more women in psychological medicine in view of their special suitability for this work. The public health services are recommended by several as affording good prospects; others note that though the L.C.C. and other municipal authorities offer openings in the lower grades of the service women still find it difficult to get promotion to the higher grades. Some express regret at the prejudice against married women in the public health services. In this connexion it is of interest that though only 10 St. Mary's women are at present working as full-time assistant medical officers of health or school medical officers 10 others have at one time held such posts, of whom 7 are now married.

In the Government services at home and abroad salary and conditions seem on the whole to give satisfaction, except where prejudice exists against married women.

Some who are working in Colonial or Dominion medical mission services stress the wide field of opportunity for those fitted for very hard work under conditions which may be difficult; in the mission services women are urgently needed, and those who plead for recruits to join in this work evidently find ample compensation for the slender financial rewards in the interest and variety of their activities.

A few extracts from the comments made are set out below:—

"Very old people seem to prefer women doctors."—  
 "Much valuable voluntary work is available for a married medical woman. . . . By doing voluntary work for some time for a Home I have induced the organisation to create a post now filled by a salaried doctor."—"It may be that men who consult women doctors do so because they are used to being doctored by their mothers."—"Children appear to be less frightened of women school medical officers than they are of men."—"Life here suits me down to the ground. I have a nice little house complete with dog and cat, some extremely good friends, my people within 20 miles, a car, lovely country all round, and I get on well with most of my patients though of course one gets exasperated with some for not paying."—"I know nothing about conditions of medical practice in the British Isles. In the more advanced tribes among whom I am now working (in the Belgian Congo) the natives come just as readily to a woman as to a man! . . . Among the more backward tribes a medical woman has far greater difficulties in getting patients than a man owing to the contempt and disdain with which women are regarded by the men and to the fact that the women more or less accept this, getting their own back at times by foul language or by starving their husbands."—"Women dental surgeons still somewhat of a novelty but a good living is to be made in dentistry."—"Women sometimes postpone going to a man if an extensive examination is needed."—"There seems to be increased confidence in medical women as obstetricians. I find that having three young children has increased rather than lessened my practice."—"In my opinion

medicine offers the best career at present open to women, married or otherwise, whether from the point of view of status or that of rewards, material and moral. A daughter of mine is about to enter the profession."

The general impression gained from the comments is that most of those who contributed to them are assured that medicine provides ample opportunities, in one or other of its branches, for women. It would seem that work is being done under conditions which are, for the most part, individually satisfactory, and that no one seeking congenial work has failed to find it.

I would like to thank Mrs. M. Cotton, M.B., Mrs. H. Davenport, M.R.C.S., Dr. Dorothy Fenwick, and Mr. Vernon, assistant secretary of St. Mary's Hospital Medical School, for their great help in the task of collecting these figures, and Mr. E. Cheeseman, of the department of epidemiology and vital statistics of the London School of Hygiene and Tropical Medicine, for assistance in the statistical tabulation.

## GENERAL MEDICAL COUNCIL

SUMMER SESSION, MAY 26-29TH, 1936

### A Question of Canvassing

*The Case of Salvatore Donadelli*, formerly registered as of Cavasso Nuovo, Udine, Italy, and now registered as of Hanbury-road, Pontypool, Mon, M.D., U.Padua, 1917, who had been summoned to appear before the Council on the following charge:—

(1) That you have behaved improperly and in a manner unbecoming a registered medical practitioner to the following patients of the practice of Thomas John McAllen, a registered medical practitioner by whom you were employed as an assistant: (*dates and names specified in five cases, witnesses A.-E.*).

(2) That after you had ceased to be employed as an assistant by the said Thomas John McAllen you canvassed for the purpose of obtaining patients in respect of a practice as a registered medical practitioner which you proposed to carry on, and in particular canvassed: (*dates and names specified in nine cases, witnesses E.-M.*); of whom all except one (*witness M.*), who was a patient of Joseph Ferguson Blaine, a registered medical practitioner, were patients of the said Thomas John McAllen.

(3) That for the purpose of obtaining for your own advantage moneys which you were not entitled to obtain while you were employed as an assistant by the said Thomas John McAllen, and/or of procuring patients of the practice of the said Thomas John McAllen to become patients of the practice as a registered medical practitioner which you proposed to carry on, you depreciated the professional skill, knowledge, and services of the said Thomas John McAllen, and in particular by doing so (*five occasions specified witnesses N., O., and some of the previous*); all of whom were patients of the said Thomas John McAllen.

(4) That for the purpose of obtaining moneys for your own advantage, and/or of inducing the patient to become a patient of the practice as a registered medical practitioner which you proposed to carry on, you depreciated the services given by Arthur Carveth Johnson, a registered medical practitioner acting under a scheme for the treatment of tuberculosis by a public authority, in advising Mrs. P. to enter an institution for such treatment, and endeavoured to persuade her to make payments to you for medicines to be supplied by you as an alternative form of treatment.

(5) That during the time you were employed as an assistant by the said Thomas John McAllen, you made false and malicious accusations of negligence against the said Thomas John McAllen to Mr. and Mrs. Q., patients of the said Thomas John McAllen, in respect of his treatment of the brother of the said Mr. Q., with a view to your

own advantage and/or in order to prejudice the said patients against the said Thomas John McAllen.

And that in relation to the facts so alleged you have been guilty of infamous conduct in a professional respect.

The complainant was Mr. Thomas John McAllen, M.B., B.S. 1907, R.U. Irel.

Dr. Donadelli attended, accompanied by Mr. Ifor Lloyd, counsel, instructed by Messrs. Davis, Lloyds and Wilson of Newport.

The complainant was represented by Mr. T. Carthew, K.C., and Mr. A. A. Pereira, counsel, instructed by Messrs. Bytheway and Son.

On the first day of the session the Council's solicitor read a letter from respondent's solicitors begging for an adjournment as Dr. Donadelli had only heard of the charge on April 29th when he was on holiday in Italy. He had returned on May 4th, and next day had written to the Medical Defence Union asking for assistance, but this had been refused as both parties were members. Only on May 13th had he learned that postponement would be opposed by complainant. He had not been idle but it had been impossible properly to prepare the case in the remaining time. Moreover, he had absolutely no English money. He was prepared to undertake not to practise in Pontypool before the hearing of the case. Mr. Carthew opposed the application, which was refused. On the third day it was urged again by Mr. Ifor Lloyd, counsel, and again refused. Opening the case on the fourth day, Mr. Carthew explained that complainant had had occasion to warn Dr. Donadelli, while he was assistant, never to see female patients alone.

#### WITNESSES FOR THE COMPLAINANT

WITNESS (Miss A.) testified that on or about May 30th last respondent had visited her mother. She had asked for advice and he had insisted she should undress and lie on the bed. He had pulled her knickers down, put his finger into her private parts, and asked if she felt pain or pleasure. He had mentioned that he was the same age as she was and had a wife who was away. She had reported the matter, and later respondent had called and asked her to deny her former statement; this she had refused to do.

Cross-examined by Mr. Lloyd, she said she lived with her parents. She could not say how long the doctor had been in the house. She might have mentioned pain in the lower abdomen as well as the sweating of which she had chiefly complained. There was no couch in the sitting-room. She had not undressed beyond loosening her corsets. She had not known he was going to examine her. He did not speak English very well and she had had some difficulty in understanding him. She had told respondent she did not accuse him of assaulting her, and had agreed to see complainant, whom she had told she did not want to make any complaint.

In reply to the President she said this occasion was the first time she had seen respondent.

WITNESS (Mrs. B.) said that her mother-in-law and herself had long been patients of complainant. Dr. Donadelli had attended them about a year ago as assistant. She was suffering from a hæmorrhage after operation and was never free from pain. Each time respondent had visited her mother-in-law he had suggested examining her and she at last consented. He had pulled the curtains and examined her in bed. He had asked if her husband gave her any sensation and said he would try and give her one. He had told her she ought not to have any more children and offered to tell her how to prevent

it. She had complained to complainant and respondent had called and reproached her, saying he only did what all foreign doctors did. About Christmas-time he had called again and said he was sorry for her as she was not being properly treated.

In cross-examination she said he had asked her how she was, while visiting her mother-in-law. She had had lower abdominal pain. The window of the bedroom opened on to the street but she did not think people could see in. She did not agree that her mother-in-law was in the doorway the whole time; she was in the kitchen armchair and the door was shut. Nor had her mother-in-law fetched soap and water; she was too old. The doctor had not used a torch or implement. She had resented his examination. She had been examined there before but not in that way. She had told him she had pain on intercourse when he asked, but had not volunteered it. She had not complained until July because she did not like to. Dr. Donadelli had attended her later, but she had sent for Dr. McAllen and had not been examined by Dr. Donadelli. She had gone to the surgery about Christmas and had consulted him about her heart. She had thought another doctor was hiding something from her about her heart and so had gone to respondent.

In reply to Mr. H. L. Eason she said she had complained to Dr. McAllen in July on her own initiative; no one had spoken to her about it.

Mr. Carthew proved the serious illness of Mrs. C. and Mr. Lloyd objected to the reading of her statutory declaration in her absence. The President ruled that it be not read.

WITNESS (Mrs. D.) said she could just write her name but could not read. She recalled sending for Dr. McAllen and being visited by Dr. Donadelli. Next visit she had said she felt no better and he had said he would examine her. She was on her bed and he put his finger in her private parts and moved it up and down and then asked if she wanted a man. She had pulled the clothes over her and had later told her husband. A couple of days later he had called again and she would not speak to him. In March, 1936, he had called to question her about complaining.

Cross-examined, she agreed that she had been in bed ill with internal pains in the lower abdomen when she had sent for the doctor. She was 61 years of age and had had a good deal of experience of doctors. The respondent had not had any flash lamp. He had used his fingers and that was the indecent behaviour she complained of; no other doctor had ever done such a thing to her. She had been very disgusted.

WITNESS (Mrs. E.) said respondent had wanted to examine her, but she had refused. He had often suggested that the doors should be locked and had said she was thin because she did not go with her husband. He had urged her to have special treatments. Later he had told her he had left Dr. McAllen and started on his own and had asked if she and her husband would give their panel cards to him.

In cross-examination she said she and her husband had been pretty friendly with Dr. Donadelli. Respondent had never assaulted her in any way. He had often been in and out of the house and had treated her for diabetes, and told her to weigh herself. He had suggested hospital, but she had refused to go at first and he had suggested injections at home and given her tablets, for which she had never paid. After March she had had to go to hospital.

Dr. E. W. Bone elicited the explanation that Mrs. E. was a club patient.

WITNESS (Mrs. F.) testified that respondent had attended her and her husband while he was assistant to Dr. McAllen. Later he had called and asked them to transfer to him as he was setting up for himself.

Cross-examined she agreed she had been very friendly with Dr. Donadelli and was not surprised that he had called to say good-bye. She knew he had been living in Dr. McAllen's house but she had not asked him where he was going to live or what he was going to do. Her husband had been present but had not inquired about a panel. She knew nothing about his practice.

WITNESS (Mrs. G.), examined by Mr. Pereira, said that respondent had called on her as assistant and offered her special treatments from Italy. He had supplied tablets for which she or Mrs. F. had paid; they had done no good. He had told her that Dr. McAllen was very skinny and would skin all his patients. Later, he had said he was setting up himself and would not skin his patients nor charge them so much. He had asked for the panel cards.

Cross-examined, she said she had had rheumatism for years and had had many bottles from Dr. McAllen; these had done her good. She was quite satisfied with the result, though she still had the rheumatism. She had not asked Dr. Donadelli for new medicine or said her present medicines had not done her good. He had told her about cachets from Italy and he had got them without her asking. Respondent knew she was not on the panel, but had asked her and Mrs. F. for panel cards.

Dr. Bone inquired about the panel cards of the family and she said that her husband was on Dr. McAllen's panel but her elder daughter was on another doctor's. When respondent had asked for their panel cards she had thought he meant Mr. G.'s and Mrs. N.'s.

WITNESS (Mrs. H.) testified that Dr. Donadelli had called and said he had left Dr. McAllen and was looking for patients and would call any time of the day or night and would attend regularly. He had said he would call again to see her husband.

In cross-examination she said respondent had attended her as Dr. McAllen's assistant. He had not called to say good-bye and she had not asked where he was living or what he was going to do. Dr. McAllen had called on her and asked her to make the statement. He had not discussed Dr. Donadelli except to ask if he had been there.

In reply to members of the Council, she said respondent "as good as" asked her to become his patient by telling her his plans and directing her to his surgery.

WITNESS (Mrs. J.) said respondent had told her he was finished with Dr. McAllen, was on his own, and was taking panel patients, and that he would call at any time and regularly.

Cross-examined, she said he had been attending her little boy as assistant; he had not called to say good-bye. She had not asked questions but he had volunteered statements. He had never come again. When she had visited the surgery in March Dr. McAllen had asked if Dr. Donadelli had invited her to become his patient.

WITNESS (Mr. K.) said respondent had attended his wife as assistant. On March 13th he had called and invited them to become his patients.

Cross-examined, he said his wife had had three visits from the doctor and on March 13th he had not exactly come to say good-bye. There had been no discussion whatever about panel cards.

In reply to Dr. Bone witness said he had been out of work for six years and had not required medical attention. He had been on Dr. Blaine's panel. His wife had been attended by Dr. McAllen as the parish doctor. Respondent did not know their circumstances.

WITNESS (Mr. L.) said his son had been attended by Dr. McAllen and his assistant. Dr. Donadelli had offered injections from Italy, saying that Italian medicine was much more advanced. He had asked money for it. He had said all the stuff in Dr. McAllen's surgery was not worth twopence. Witness had refused the treatment for fear Dr. McAllen would subsequently have nothing to do with them. Later, respondent had called and said he had finished with Dr. McAllen and could see patients at another address.

Cross-examined, he said he had asked Dr. McAllen, his panel doctor, to call and he had done so and advised hot water treatment and a lotion; and later some ointment. He had been quite satisfied with the treatment. The disease had begun in November and the child had had it five years before. He did not remember respondent saying the boy had acidosis and needed something beyond local applications. Witness was accustomed to getting his medicines from the surgery and respondent had said the injections would not be found in the surgery and Dr. McAllen would not agree with them because they were too expensive.

WITNESS (Mr. M.) testified that he lived with his mother and was a patient of Dr. Blaine but Dr. McAllen was his mother's and his brothers' doctor, and Dr. Donadelli had attended his mother as assistant. He had called at the shop and announced that he was taking panel and private patients on his own. Witness had said he did not think Dr. McAllen charged his mother anything. Respondent had said he was very cheap, and would charge 3s. 6d. a quarter for a husband, wife, and child.

WITNESS (Mrs. N.) said she had been present every time respondent had called on Mrs. G. and corroborated that witness. He had supplied medicine to her daughter and had been paid for that and also by Mrs. G. He had said Dr. McAllen had nothing in his surgery that would do her any good but that he could get medicine from Italy that would cure her. Mrs. G. had been in great pain but had been quite satisfied with Dr. McAllen's treatment. Her daughter had not exactly asked him for medicine for her child but had said the little girl was ill and he had offered to get medicine from Italy. Her daughter had said it did not matter what it cost if the child got well, and he had supplied six bottles for 9s.

WITNESS (Mr. O.) testified that Dr. McAllen had attended his family for over 17 years. Dr. Donadelli had called to see him, as he had sciatica, and had said the medicine was no good and was only crushed aspirin and had offered better medicine but said it would cost money. Witness had decided he could not afford the £1 asked.

Cross-examined, he said he had been away from work for ten weeks with sciatica. Dr. McAllen had sent him two bottles at the beginning of his illness. He had wanted to get back to work but had not told Dr. Donadelli he wanted another medicine to

get him well faster. He had been in pain for about a week at that time. The doctor had told witness to put a £1 postal order in a plain envelope with a 1½d. stamp, in order to send it away somewhere.

In reply to Dr. Bone, he said his panel doctor was Dr. Blaine, and Dr. McAllen was his works doctor, whom he paid through the poundage system. He had seen Dr. McAllen at the surgery and got the medicine there.

#### COMPLAINANT EXAMINED

Dr. McALLEN said he had a large panel and private practice and was parish doctor and doctor to the urban district authority. As a result of complaints, he had given Dr. Donadelli notice. Later he had heard many complaints of canvassing and improper behaviour. He had himself seen Dr. Donadelli's plate up at Blaenavon, about 5½ miles from the centre of Pontypool. When he had first received the complaints he had been asked by his other assistant to give Dr. Donadelli another chance because the continental outlook was so different and what would be regarded as improper conduct here would be disregarded in Italy. Witness had made him promise not to examine another female patient alone. This promise he had kept. He had had no right to receive cash; most of the practice money came from the works and the rest from six-monthly accounts.

Cross-examined, he said respondent had himself asked for six weeks' probation at the beginning of his engagement on April 25th, 1935. He spoke English very well for a man who had only been two years in the country. The first complaints had been made a few weeks after engagement, within the probationary period. He had not the faintest idea how many patients Dr. Donadelli saw in a day; it might be thirty in a morning. The practice was an extensive working-class one. He himself had never found any kind of examination embarrassing. His other assistant had lived on the continent as a student. He could not say if there was more stiffness and reticence in this country than abroad. Despite the complaints, he had kept respondent on as a result of the other assistant's explanations. He had not regarded the matter as merely gossip. There had been no more complaints until after respondent had left. He had given notice on Feb. 11th and dismissed Dr. Donadelli summarily on Feb. 24th because he had been getting money from patients. None of those who had appeared at the hearing had complained before this notice. Respondent had been given at that time the name of one patient from whom he was said to have demanded money. In the agreement, witness was to pay respondent £75 a year for the use of his car. When notice was given witness had told him not to use the car for the last month; but this had not been just to save paying the allowance. Mr. L. had told his story between 9.30 and 11.30 on Feb. 24th. About 12.15 witness had seen respondent and said he was not to use his own car for the afternoon visits but to be driven to the end of the town in witness's car and to walk back. He had not dismissed him because he had used his own car in defiance of orders. He had never heard of Dr. Donadelli's war wound. He was not aware that he had no right to stop the car allowance as it was part of the contract. He had heard Mr. L. testify that he had not complained till the 29th, but still maintained that he had dismissed Dr. Donadelli because of Mr. L.'s report on Monday the 24th. He had, he admitted, gone round asking about complaints of canvassing. He and Dr. Donadelli

had disagreed about the treatment of patients from time to time. He had never insisted that prescriptions must be limited to drugs in the surgery. He had never seen a plate of Dr. Donadelli's in Pontypool. He did not know that he had been assistant and had tried to buy a practice in Blaenavon.

In reply to the legal assessor he said he had stopped the car allowance because respondent had claimed to have visited three patients whom he had never seen; witness had therefore sent his own chauffeur with him.

In reply to Dr. Bone and other members, he explained the poundage system and that it included supply of medicines. His dispensary was adequately equipped. He did not say he ought to have received the money himself; his case was that no money ought to have been taken from those patients and that was the cause of the dismissal. He agreed that the examining doctor was the best judge of the need for vaginal examinations and that patients sometimes objected to quite proper examinations.

No evidence having been offered on the last two charges, they were dropped.

#### RESPONDENT EXAMINED

Dr. DONADELLI said he had never committed any impropriety with any patient. Miss A. had complained of sweating and pain in the lower abdomen and back, and had asked him to examine her. She had undressed and he had examined the heart, the abdomen, and then the vagina with an illuminated speculum. He considered the examination necessary. He had asked if she felt pain—not pleasure. He had never discussed his wife and family. She had made no protest at the time. Dr. McAllen had later told him to go and investigate a complaint she had made. She had said she would herself go to Dr. McAllen and explain that she made no accusation of assault. Mrs. B. had been suffering severe lower abdominal pain and hæmorrhage and had asked him to examine her, as she was getting no better. He had examined her on a couch, with the mother-in-law in the room. She had complained of dyspareunia and he had examined her with his fingers and a torch. He had advised her to avoid intercourse until she recovered and had advised disinfectant douches. She had asked whether it would be harmful for her to have children and he had advised against it. She had shown no resentment. Later on she had visited him privately, saying she did not trust the hospital or other assistant but trusted him. Mrs. D. had been in bed with pain in the abdomen and back when he saw her. He had examined her vagina with speculum and torch. He had seen both her and Mrs. B. many times after. He had not asked her if she wanted a man. He had advised douching. Mrs. E. he had only examined once, and that in the presence of a friend. He was friendly with the members of the household and had visited often; he had never suggested locking the doors. He had advised insulin; she had refused to go to hospital. He had given her two boxes of anticoman tablets; there were no such tablets in the surgery, and he got them free as samples from the manufacturers. Neither she nor anyone else had paid for the tablets. Mrs. E. had known quite well that he was not opening a surgery in Pontypool; her husband had recommended him to a vacant club practice a little way off. She had sent a friend of hers to witness, but he had refused to see her because she lived in Pontypool. When Dr. McAllen dismissed him he had found a bedroom to live in but had had no surgery there. It was not true that he had asked Mrs. F. for panel cards. It

had never been his intention to stay in Pontypool and he had tried the area around. He had visited a number of patients to say good-bye in a friendly way and they had asked him his plans. At that time he had no practice at all. There was a practice in the market at Blaenavon and he was negotiating for its purchase, and meanwhile practising there. The people of Pontypool would never go to Blaenavon for a doctor. It would have been useless for panel patients to transfer in March as the month's notice would have had to be given at the end of February. For the boy with dermatitis he had suggested calcium injections, which he had known only in Italy. The father had asked if he could get them at the surgery; witness had replied that he could not, and they were expensive. He had seen Mr. L. on a Monday (24th), the day he was dismissed, and had not called next day. He had seen Mrs. N.'s granddaughter who was having medicine from Cardiff. He had recommended a medicine he had used in Italy and she had asked him to send for it and asked the price. He had sent for it from Italy and had made no profit. It was not available in Pontypool. Mrs. G. had tried various medicines from the surgery without benefit and she had asked him to find something else for her. He had got cachets for her from Italy; they contained benzoate of soda, coramine, and other substances. To Mr. O. he had first said that Dr. McAllen wanted him to use only medicines in the surgery and nothing else, but as these were doing no good he had mentioned certain injections which could be obtained from a Newcastle chemist. He had intended the patient to send the money direct, and had never meant to handle it himself at all, but the patient had decided against the treatment.

Cross-examined by Mr. Carthew, he admitted that he had called on over a hundred patients to say good-bye. He knew that the women paid Dr. McAllen through contracts. He had told Dr. McAllen that the medicines in the surgery were insufficient, but had not told him he was taking money from patients for medicines. He did not think it was a grossly improper thing to do. Dr. McAllen had wanted to get him deported. He had no receipts because his family had bought the drugs for him in Italy.

Witness answered questions by members of the Council about his visits to patients and said he had lived in Pontypool from Feb. 25th to April 2nd or 3rd.

#### COUNCIL'S DECISION

After brief deliberation in camera the President announced that the Council would confine its attention to charges 2 and 3. Mr. Lloyd addressed it on behalf of his client, and Mr. Carthew spoke briefly. After a short period of deliberation the President announced that eight of the nine items of charge 2, and four of the five items of charge 3, had been found proved, and the Registrar had been directed to erase Dr. Donadelli's name from the Register.

ROYAL SAMARITAN HOSPITAL FOR WOMEN, GLASGOW.—A new wing, for paying patients, at this hospital was opened on May 28th by Sir John Stirling Maxwell. The accommodation in the new wing consists of two wards of 12 beds each, and six rooms with single beds. The single rooms are intended for serious cases, and no difference is to be made in the charge for a bed in the single rooms and a bed in the wards. Through the Outram Press Fund, every bed is fitted with wireless. The fees are graded from eight guineas in the first week to three guineas in the fourth and succeeding weeks.

## MEDICINE AND THE LAW

### Damages Against Surgeon

THE judgment of Mr. Justice Finlay in *Dryden v. Stewart and the Surrey County Council* (see THE LANCET, April 25th, p. 969) will satisfy neither the patient nor the surgeon. Mrs. Dryden alleged that plugging was negligently left in her body after an operation. She claimed damages both against Dr. John Stewart, who had performed the operation, and against the county council in whose hospital she was treated and by whose nurses she was attended. The judge thinks that she exaggerated her story but did not go so far as to invent it; he has held that the plugging was inserted at the time of the operation and he can see no other explanation than that the surgeon inserted it and afterwards forgot that it was there. The judge awards £250 damages against Dr. Stewart; but, as he dismisses Mrs. Dryden's claim against the county council with costs, she may have to pay much more than she will receive. The judgment is of great importance to hospital committees as it may deter similar claims in future. First, however, we must deal with the case against the surgeon.

Mrs. Dryden was married in March, 1934. In the following August she became pregnant and in November had an accident which caused a miscarriage. The placenta remained in, and her regular medical attendant, Dr. Keble, advised her to go into the county council's hospital at Epsom. Here the placenta was removed by Dr. Stewart; the operation was followed by a douching, and Mrs. Dryden went home after about a week in hospital. Dr. Keble saw her on her return: she then complained of soreness, bruising, pain, and a discharge. Two days later, as she found it impossible to douche herself, Dr. Keble examined her and extracted what the judge referred to as a "black evil-smelling sausage of surgical gauze," tightly packed and extremely foul. Dr. Keble's evidence was that the state of this compressed and offensive mass was consistent with its having been inserted in the body nine days before—i.e., at the date of the operation. Three days later Mrs. Dryden went into the Kingston Hospital: here further plugging was removed by one of the sisters. She left hospital, returned to it in December, and in January, 1935, went back to work and had been at work ever since but complained of pain. The plaintiff's case was that she contracted pyelitis and cystitis and that the pyelitis might recur. The judge dealt carefully with the medical practice of plugging as discussed in the medical evidence. It was clearly proper, he said, to plug in the case of excessive bleeding, either actual or apprehended. Some surgeons always plugged; others, especially the younger members of the profession, did not do so habitually. Dr. Stewart, said the judge, was perfectly definite that he did not plug in this case; there was certainly no reference to plugging in the chart or records; all persons present said they saw no plugging used. But it was clear that plugging had been taken out as described by Dr. Keble. If Dr. Stewart did not insert it, the patient herself must have done so. Mr. Justice Finlay, while not favourably impressed with some of Mrs. Dryden's evidence and while of opinion that she displayed an undoubted animus against the nurses in the Epsom Hospital, did not think she was putting forward a deliberately false case—"and that, and nothing but that, is what she was doing if she put this plugging

in herself." He did not see what motive she would have had in plugging herself and, though he bore in mind the evidence of Mr. Hedley (to which he gave great weight) that women can and sometimes do plug themselves, the difficulties of holding that Mrs. Dryden did so seemed to be insuperable. "I feel constrained to find that the defendant doctor did put in this plugging and then by an unfortunate lapse of memory forgot it." It was reasonably established that the pyelitis and cystitis were due to the presence of the foreign body and that in any future pregnancy there would be more risk of them. Mrs. Dryden had made a good recovery and had substantially been well since her return to health. For her pain and suffering, and for the possibility of future trouble, £250 was, in the judge's view, a proper sum to award.

In the case against the Surrey County Council there were questions of law as well as of fact. The judge reviewed the well-known decisions (including *Hillyer v. St. Bartholomew's Hospital*) and adopted the language lately used by *Horridge, J., in Strange-ways-Lesmere v. Clayton*. The committee of a hospital contracts with a patient that they will provide a hospital, that is, an appropriate building suitable for the purpose, with a domestic staff which they will control; they also contract that they will employ or engage competent doctors and competent nurses, but they do not undertake to be responsible for the way in which the doctors or nurses perform their duties. Those duties, Mr. Justice Horridge had said, are the duties of skilled people; the actions of doctors and nurses cannot be controlled by members of a hospital committee who do not pretend the knowledge or ability to perform those duties themselves. Even if the nurses at Epsom had been proved guilty of negligence, it would (said Mr. Justice Finlay) be negligence in carrying out their skilled duty as nurses and it would not be negligence for which the county council could be responsible. Mrs. Dryden had alleged that the hospital staff was incompetent and the ward understaffed. The judge rejected these statements. There were 54 beds in the ward with one staff sister, one staff nurse, and five well-advanced probationers; the mere presence of probationers was no evidence of negligence. Patients might not receive in a ward the same individual attention as a rich person may pay for in his own home. The judge accepted the evidence of one of the sisters that the nurses, though busy, were not overworked. Although Mrs. Dryden said she complained of a black, foul-smelling discharge on her first return from the hospital, Dr. Keble had not detected it till he extracted the gauze. The nurses could not be held negligent for not having discovered what the hospital doctors did not observe and Dr. Keble did not at first detect. Plaintiff's counsel conceded that there was nothing to fix the nurses with knowledge that the plugging was in; they could therefore have had no duty to remove it.

One other point may be mentioned. There was an argument over the appropriate order against Mrs. Dryden for the costs of the county council. The latter body had the advantage of the Public Authorities' Protection Act, which apparently would mean that she would have to pay its costs as between solicitor and client, a much heavier liability than the ordinary scale of taxed costs. Mrs. Dryden's counsel asked the judge to deprive the county council of costs because it had refused, in the earlier stages of the litigation, to allow her lawyers to interview the nurses at its hospital. This refusal, it was argued, was

bound to inflame suspicions and to encourage the plaintiff in pursuing her rights. Mr. Justice Finlay thought that, if the county council had made a mistake in refusing to allow the nurses to be interviewed, it was not such a mistake as would justify him in depriving the county council of costs or in loading these costs on to Dr. Stewart. The claim against the county council failed on the law as well as on the facts; the allegations of negligence against the defendant doctor were different from those against the defendant county council, so that it was not fair to saddle Dr. Stewart with the whole bill. A stay of execution against Dr. Stewart was granted on the usual terms that he gave notice of appeal within 14 days and brought the money into court. There may thus be further judicial discussion of the case against the surgeon. On the case against a county council, as the body responsible for a hospital, more will be heard when the House of Lords at length completes the hearing in *Marshall v. Lindsey County Council*.

### Dangerous Treatment of Rheumatoid Arthritis

At an inquest held last week by the Birmingham city coroner, death was apparently attributable to the too continuous use of gorun, prescribed as a remedy for rheumatoid arthritis. The deceased, a woman of 50, had suffered acutely for several years and was obliged to use crutches. A friend recommended treatment by Dr. H. Jacobson, a German doctor in Golders Green, who had made a successful cure. Dr. Jacobson saw the patient in the presence of her own medical attendant and, after examining her, recommended the drug. Her medical attendant obtained it from his usual chemists; after a properly cautious inquiry from them and from consultants, he was assured that it was harmless. He injected the drug twice a week until he found the patient's skin turning yellow. He was unaware that the preparation contained atophan; had he known this he would have realised that the treatment should be intermittent and not continuous. Post-mortem examination indicated acute yellow atrophy and necrosis of the liver. Among the witnesses who gave evidence before the coroner, Prof. P. C. P. Cloake of Birmingham University described gorun as a mixture of three drugs, one of them being atophan. It was a valuable remedy but must be given intermittently. The later literature issued with the drug contained a note as to the method of administration: the witness thought the warning inadequate. Dr. Jacobson, who was questioned through an interpreter, told the coroner that he was responsible for the formula of gorun which he had used for many years in Germany and had introduced into England in 1923. It contained 1 per cent. of atophan. Asked by the coroner why the warning note had not appeared in the literature issued to the deceased's medical attendant on the purchase of the drug, Dr. Jacobson said the note was added after a fatality in England a few years ago. He thought he had told the deceased's doctor that the doses should be intermittent. Another witness stated that medical practitioners might have difficulty in recognising atophan under the name phenyl-quinolin-carboxylic acid which appeared in the formula on the box. The coroner recorded a verdict of death by misadventure. He observed that the drug had been administered in good faith after consultation with the author of the formula and with the supplying chemists. The coroner had no hesitation in saying that in future the distributors ought to supply much more explicit instructions,

especially if the treatment was likely to be prolonged in chronic cases.

On one point of general procedure there was a difference of opinion between the coroner and Prof. Cloake. The latter had held a post-mortem examination at the hospital and propounded the view that an inquest was unnecessary. The coroner asked him whether he knew of any substitute for an inquest which would be likely to obtain the same amount of publicity for facts which ought to be known. The medical attendant of the deceased had been unaware that he was administering a drug which contained atophan. Prof. Cloake answered that the proper nomenclature and disclosure of the ingredients of a preparation were a legal question; the law had apparently been complied with. The coroner did not go so far as to charge the professor with obstructing the inquest or tampering with the evidence. He was, however, clear that this was a "coroner's case" and not one for a private post-mortem examination without facilities for the attendance of relatives. Prof. Cloake continued to dispute the point and denied the right of the coroner to express such opinions to a witness. Without taking sides in this controversy on procedure, we can all unite in advocating full notice of any dangerous property in drugs which, however beneficent, are unfamiliar. If treatment is dangerous unless intermittent, the instructions should say so.

### Conviction of Murder by Weed-killer

Charlotte Bryant was convicted at Dorchester assizes last week on the charge of having murdered her husband by administering arsenic to him. The deceased, a cowman, died in Sherborne Hospital on Dec. 22nd last. The Crown asked the jury to believe that he had at least two other illnesses and that all three were due to arsenical poisoning. The evidence of Dr. Roche Lynch established the cause of death. He found the organs of the deceased in a pinkish and inflamed state, and they were remarkably well preserved six days after death. He discovered arsenic in every organ he examined; he estimated that the body contained 4.09 grains of arsenic. The presence of arsenic in the finger-nails, to the amount of 33 parts per million, supported the view that the illnesses of August and December were attacks of acute arsenical poisoning. The witness could not speak as to arsenical poisoning in relation to the illness of the previous May. Mr. Justice MacKinnon told the jury that it was almost impossible that Bryant could have administered the arsenic to himself. No sane human being, having endured the agony of one attack, would subject himself to another. The poisoning might be accidental but the accident would have had to happen a second and third time. If the arsenic was neither self-administered nor accidentally swallowed, it must have been given him by somebody else: Mrs. Bryant was the only person (except for her children) who was living in the house during each of her husband's three illnesses in May, August, and December of last year. A possible motive was her intimacy with a witness named Parsons to whom she was said to have spoken of the prospect of her widowhood and remarriage. A tin of weed-killer was suggested as the source of the poisoning. Nobody could give evidence of Mrs. Bryant having bought arsenic or weed-killer, but a battered tin was found which a tin-box manufacturer stated was similar to the tins made by his firm for a weed-killer company. Dr. Roche Lynch analysed scrapings from this tin and found 58,000 parts of arsenic per million. He also examined sifted ashes

from under the copper; in these he found 149 parts of arsenic per million though coal ashes normally contained no higher proportion than 50 parts.

The defence was able to emphasise the absence of direct evidence. Both in May and August a doctor was called in by Mrs. Bryant to attend her husband in his attacks of illness. The doctor, "the very

man of whom a murderess would have the greatest fear," was again summoned when the third illness occurred last December. This fact, and the failure to prove the purchase of weed-killer by Mrs. Bryant, were strong arguments in favour of her innocence. The jury, consisting of men only, found her guilty after deliberating for an hour.

## PANEL AND CONTRACT PRACTICE

### An Unrecognised Surgery

A PRACTITIONER who had a surgery for insurance and private patients, the existence of which he had not divulged to the insurance committee, has received a reminder that such things are not done. He has been on the medical list since 1913 and until 1926 he had two addresses at which treatment for insured persons was provided. During that year he applied for the committee's consent to the employment of an assistant and, as is usual, the surgeries were inspected when their condition was "such as not to meet with approval." The practitioner said his landlord had failed to have the branch surgery renovated, and he was not prepared himself to spend money on it; so with the approval of the committee the branch surgery was deleted from the medical list. From 1926 until last March the committee had no knowledge that the branch surgery was being used, but on the latter date, as a result of information received, a visit was paid to this surgery when it was found that the practitioner's assistant was conducting insurance practice there. The medical service subcommittee were satisfied on investigation that insurance medical practice was resumed at the branch surgery within a short time after its discontinuance had been notified; in fact, the practitioner did not seek to establish that it had ever been discontinued. The practitioner admitted he was ashamed of the condition of the surgery. He had, he said, done his best to discourage insurance practice at the surgery, and for a time had exhibited a notice requesting patients to attend at his principal surgery, but circumstances had been too strong for him; there was a certain amount of private practice at the branch surgery, with which he had been associated for 30 years, and he had retained the premises for sentimental as well as for business reasons. The subcommittee reported that the question they had to consider was not so much the propriety of the practitioner having a surgery in such an unclean condition—described elsewhere as squalid—as his having carried on practice at a surgery which he had notified the committee had been relinquished. The conditions under which this practice had been carried on were in their opinion such as to bring the insurance medical service into disrepute. The insurance committee has suggested to the Minister a fine of £50. It would have been much cheaper to put the surgery in decent condition.

### Trouble Over a Strangulated Hernia

The sister of a deceased insured person complained of the way her brother had been treated by Dr. A and his assistant Dr. B. The patient had suffered for some years from the effects of hemiplegia and had frequently attended at Dr. A's branch surgery in order to obtain treatment which usually consisted in the provision of liquid paraffin. On March 17th he was not as well as usual, complaining of weakness in the legs, and constipation, and was seen by Dr. B. On March 21st Dr. B was again sent for and found similar symptoms, slightly more marked, but no

cause for alarm. A hernia from which the man had suffered for some years was examined and found to be easily reducible. On the following evening the patient was not so well and at about 9 P.M. attempts were made to secure the attendance of Dr. A or Dr. B, but neither was available immediately. Eventually Dr. C was called in at about 10.15 P.M., but he could find no symptoms but weakness and flatulence, and noted the hernia which was still reducible. He did not take a serious view of the case and gave merely a placebo. About half an hour later Dr. A called and formed the opinion that the trouble might be of a cerebral character—particularly having regard to the previous history and to the fact that he found the patient's pupils did not react to light. He too examined the hernia, which he found large, but reducible, and having learned of the treatment prescribed by Dr. C he contented himself by suggesting hot fomentations if there should be any pain in the hernia, and said he would arrange for Dr. B, who had been treating the patient, to call next morning. Dr. B was called from his morning surgery to see the patient next day about 10 o'clock and found him suffering from a badly strangulated hernia and said the only chance, which he described as one in a thousand, of saving the patient was an immediate operation in hospital. He accordingly issued a request for admission to a local hospital but on arrival there about noon it was found impossible to operate and death ensued about an hour and a half later. The sister's contention was that the patient should either have been sent earlier to hospital or else, in view of the fact that death was apparently inevitable, that he should not have been sent at all.

The medical service subcommittee pointed out that between the morning of Saturday and the evening of Sunday three different medical practitioners examined the patient and could find nothing suggesting the possibility of the development of the trouble which actually caused his death. They thought Dr. B was right in advising removal to hospital on the Monday morning. He knew it was extremely unlikely that anything could prevent an early and fatal termination of the illness, and had he refrained from sending the patient to hospital he might quite well have been accused of having failed to avail himself of the only possible chance, however remote, of prolonging the insured person's life. But it is doubtful whether the sister will be really satisfied with this perfectly proper decision.

LONDON HOSPITAL.—At the quarterly court of governors of this hospital on June 3rd, Sir William Goschen, the chairman, said that the progress of the £80,000 appeal was disappointing. So far only £17,679 has been received and promised. It had also proved impossible to proceed with the scheme for the provision of pay-beds for those of moderate means as the response to the appeal for this object had amounted to £16,000, including the late Lord Woolavington's gift of £10,000. A further £5000 is needed before a start can be made.

## OBITUARY

**HAMILTON GLELLAND MARR, C.B., M.D.,  
F.R.F.P.S. Glasg.**

THE sudden death of Dr. Hamilton Marr came as a shock to his many friends. He appeared to be in his usual health and was tending some flowers in his garden in Edinburgh when he was seized with a heart attack and died within a few minutes. Dr. Marr retired only last October from the office of senior medical commissioner of the General Board of Control for Scotland, and had hoped that rest from his official duties would allow him to devote his time to scientific and literary writing.

Born in Govan in 1870, the son of Hamilton Marr of Mauchline, Ayrshire, he was educated at Glasgow High School and at Glasgow University, where he graduated in medicine at the age of 22. From the outset of his medical career he was attracted to the study of mental and nervous disorders, and after spending a few years as assistant physician in the Crichton Royal Institution, Dumfries, and the Glasgow District

DR. MARR

*[Photograph by Bacon & Sons]*

Asylum, Woodilee, Lenzie, he was appointed superintendent of the latter institution in 1901. He became lecturer in psychological medicine in St. Mungo's Medical College, Glasgow, and extramural lecturer in mental diseases in the University, and his lectures attracted many students, not a few of whom fell under his influence and afterwards looked upon him as guide, counsellor, and friend. He was appointed H.M. medical commissioner in lunacy for Scotland in 1910, and subsequently senior medical commissioner for the General Board of Control. Both as medical superintendent and as commissioner his work was characterised by ceaseless energy and scientific enthusiasm which brought him the respect of his students and the esteem of his colleagues. During the late war he served as specialist in mental diseases to the troops in Malta and later as consultant in nervous and mental diseases to the Scottish Command; he held honorary rank in the R.A.M.C. as lieutenant-colonel.

In 1927-28 Dr. Marr was president of the Royal Medico-Psychological Association and gave an address entitled Dante and Rabelais, an Account of Two Medieval Physicians, with a summary of their philosophy. Two years ago, when he delivered the James Watson lectures before the Royal Faculty of Physicians and Surgeons of Glasgow, he took as his subject Madness in Literature and Life. His publications included "Psychoses of the War" and many articles on insanity and mental deficiency. "Throughout his whole career," writes a medical friend, "he was a keen searcher after truth. He travelled extensively abroad and was a student of French and

Italian literature. In long striving to improve the conditions of asylum administration in Scotland he did not always see eye to eye with his colleagues, but he was definite in his opinions and his work was characterised by sincerity."

Dr. Marr was created C.B. in 1932. He is survived by his wife, who is a daughter of the late Mr. John Mitchell, rector of Elgin Academy, and by a son and daughter.

Dr. JOHN HOWARD WRIGHT, whose death from typhoid on May 30th at Tientsin was announced in our last issue, went out to China for the London Missionary Society in November, 1922. He was educated at King Edward's School, Birmingham, and Edinburgh University, taking his medical degree in 1921. He was stationed first at Siaochang and at Tsangchow where he was in charge of the Roberts Memorial Hospital. On his transference to Tientsin he did fine work in developing and increasing the equipment of the Mackenzie Memorial Hospital there, which now has a staff of 3 Chinese doctors and 39 nurses, and last year treated 1725 in-patients and 27,875 out-patients. Dr. Wright married Miss Margaret Burnett Aitken, of Edinburgh, and leaves his widow with two children. He was in his 40th year.

Dr. ALBERT ERNEST COPE, who died in London on June 5th at the age of 68, was well known as public vaccinator for the City of Westminster and hon. secretary of the Association of Public Vaccinators. Born at Chesterfield, the son of Rev. Thomas J. Cope, he was educated at Mansfield and Hull, qualifying in medicine at Newcastle in 1889. After holding a resident appointment at the Royal Infirmary he came south to be R.M.O. at the Westminster Dispensary and remained in practice in the borough throughout his life.

Dr. ERNEST WOODHEAD BLACKBURN was the younger of two medical sons of Dr. John Blackburn, sometime mayor of Barnsley, who have maintained the tradition of general practice in that town for 75 years. He took a first class in natural science at Oxford before his clinical study at St. Bartholomew's Hospital, from which he qualified in 1895. Before returning north he was resident at the Radcliffe Infirmary, Oxford, and demonstrator of pharmacology in the University museum. In the following year, when the borough police force was established in Barnsley, Dr. Blackburn was appointed surgeon to it and he only resigned the appointment a few weeks ago. For many years he was also surgeon to the Beckett Hospital. He died on May 25th at the age of 68.

**AN ADDITIONAL TELEPHONE SERVICE.**—At a dinner of the Head Postmasters' Association held at Cardiff on May 29th Major Tryon, the Postmaster-General, said he proposed shortly to introduce a new service as an experiment in Liverpool. The subscriber would be able to inform the telephone exchange that he would be absent for a certain period and ask that callers should be given a brief message such as the reason for his absence and the time of his return. The telephone exchange would also keep a note of the telephone numbers of those who called the subscriber and to whom his message was given. The charge for the new service would be 6d. for each occasion up to 24 hours, and there would also be a contract rate. The proposed medical telephone exchange at Johannesburg described in THE LANCET of May 23rd (p. 1217) shows how this idea may be specially adapted for the medical profession, but the more general scheme to be tested in Liverpool should also prove of value.

## CORRESPONDENCE

## THE STORAGE OF BLOOD FOR TRANSFUSION

To the Editor of THE LANCET

SIR,—Your leading article last week marks the initiation of interest in the employment of cadaveric blood in western medicine; as you say, research in this subject is overdue. On the other hand preserved blood from "universal" donors was employed by a number of surgeons during the war, myself among them. From the latter part of 1917 onward, performance of blood transfusion prior to amputation of a limb was a routine measure, which reduced the mortality-rate for amputation of the thigh by over 14 per cent. in the base hospital of which I had surgical charge. It will be realised that the reservoir of donors was of variable capacity; for this reason, following the experience of Captain Robertson, of the Massachusetts General Base Hospital, American Army, a supply of citrated preserved blood was kept at hand continually; actually the stock was not allowed to fall below six Winchester quarts. As no cold-storage facilities were available, 10 minims of chloroform were added to the Winchester as preservative, and the blood decanted for use; the sterility was controlled by weekly examinations. To the best of my recollection our experience tallied with that of Robertson, that the preserved blood was valid for use up to 28 days; no incompatibilities, or reactions more severe than those met with in recently citrated blood, were encountered.

Specimens of blood which had been preserved for two months were sent, I think, to Prof. L. E. Bayliss for examination: he wrote that these appeared to have developed an excess of a toxin of the histamine group, but that some histamine was present in all

citrated blood. For this reason, whole blood, uncitrated, and given via the paraffin-coated tube, was normally employed. I had records of over 400 cases thus transfused; and have often felt that the credit of the introduction and spread of transfusion in the British Army was not given where it belonged—viz., to Mr. D. W. Crile, nephew of his famous uncle, who popularised it in the base hospitals in the Étapes area as early as 1915.

I am, Sir, yours faithfully,

Sunderland, June 4th. W. GRANT WAUGH.

## DISEASES OF THE PERIPHERAL ARTERIES

To the Editor of THE LANCET

SIR,—The recent review (May 2nd, p. 1012) of my book, "The Diagnosis and Treatment of Diseases of the Peripheral Arteries," prompts me to offer the opinion that the reviewer has evidently been guilty of one or more amputations in thrombo-angiitis obliterans, which I so heartily condemn. My efforts to establish the conservative therapy of this disease in America have apparently not been felt in England as yet. However, having already successfully overcome these stages of opposition in America, I feel sure that it will be only a matter of time when a conservative attitude toward these diseases will be forthcoming in our English colleagues.

I am, Sir, yours faithfully,

New York, May 29th. SAUL S. SAMUELS.

\*\*\* Our review questioned how far conservatism can be carried in the patient's interests. The point at which severe suffering is best ended—even at the cost of a mutilating operation—must be left to individual judgment based on a knowledge of end-results. We hope Dr. Samuels will provide further information about the subsequent efficiency of the limbs he has saved from amputation.—ED. L.

## PUBLIC HEALTH

## The Cost of Syphilis in an Urban Community

IN times of economic depression communities as well as individuals have to look to their bank balances and consider whether and where expenditure can be reduced, and whether the money they spend can be put to more effective use. The public health services are no exception to the rule, though it may be a difficult, if not impossible, task to measure their value to the community in terms of pounds, shillings, and pence, especially with regard to particular items: what does ill-health cost the community? how much of it is preventable and at what expense? One item in this account has been recently made the basis of a study<sup>1</sup> carried out in Baltimore by Drs. W. C. Thompson, W. A. Brumfield, and Lucile Caldwell of the syphilis division of the medical clinic, Johns Hopkins Hospital. The authors' object was to obtain an accurate estimate of the cost of syphilis in a representative American community, and to see whether the amount spent is adequate to deal with the existing problem, and so allocated as to provide "the combination of maximum benefit for the infected patient and maximum protection for the public health."

The investigation was carried out by an analysis of the clinical records of hospitalised patients and by means of cost data of hospital treatment, ambulatory

clinics, serologic laboratories, and cost of drugs in the year 1933. Patients privately treated were ignored. In Baltimore, with a population of about 828,000, they report that some 9000 new syphilitic patients are discovered yearly, of whom about 4000 have early syphilis and 5000 have late syphilis. The total *direct* cost of that burden in 1933 they assess roughly at \$170,000, or, in other words, each new syphilitic patient is responsible for the charitable expenditure of more than \$18 per year. A study of the age-distribution of the hospital patients showed that nearly three-quarters of them were under the age of 50; as 74 per cent. of the hospital costs were for cardiovascular and neurosyphilis, which usually lead to prolonged invalidism, the authors conclude with reason that most of these patients, in the prime of life, are permanently removed from the possibility of self-support and form an annual charge.

On the other hand the sum available for ambulatory clinics they regard as quite inadequate and for many patients they find no treatment at all is available. They urge that if that sum were substantially increased much of the cost of hospital care would be obviated, since the late sequelæ of the disease would be prevented and fresh infections reduced. They thus reach the undeniable conclusion that "only by a reduction in the incidence of syphilis can the total expenditure be reduced," and the reasonable though, perhaps, less certain corollary that "only by the

<sup>1</sup> Amer. Jour. Syph., May, 1936, p. 243.

provision of adequate ambulatory clinics can the incidence of syphilis be reduced." In general, they believe that health departments give to the venereal diseases far less attention than they deserve, both from the patient's and the community's point of view.

### INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED  
MAY 30TH, 1936

**Notifications.**—The following cases of infectious disease were notified during the week: Small-pox, 0; scarlet fever, 1795; diphtheria, 879; enteric fever, 46; pneumonia (primary or influenzal), 806; puerperal fever, 42; puerperal pyrexia, 106; cerebro-spinal fever, 22; poliomyelitis, 7; encephalitis lethargica, 12; dysentery, 26; ophthalmia neonatorum, 104. No case of cholera, plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the London County Council on June 5th was 5031, which included: Scarlet fever, 1061; diphtheria, 756; measles, 1944; whooping-cough, 566; puerperal fever, 16 mothers (plus 11 babies); encephalitis lethargica, 284; poliomyelitis, 1. At St. Margaret's Hospital there were 27 babies (plus 15 mothers) with ophthalmia neonatorum.

**Deaths.**—In 122 great towns, including London, there was no death from small-pox, 1 (0) from enteric fever, 47 (18) from measles, 5 (0) from scarlet fever, 32 (6) from whooping-cough, 32 (5) from diphtheria, 40 (11) from diarrhoea and enteritis under two years, and 31 (8) from influenza. The figures in parentheses are those for London itself.

Southampton, Hull, and Birmingham each reported 3 deaths from measles, no other great town more than 2. Birmingham had 4 fatal cases of whooping-cough, Liverpool 3. Deaths from diphtheria were reported from 19 great towns, 4 from Sheffield, 3 from Bradford.

The number of stillbirths notified during the week was 290 (corresponding to a rate of 40 per 1000 total births), including 51 in London.

## THE SERVICES

### ROYAL NAVAL MEDICAL SERVICE

Surg. Lts. C. Ommaney-Davis and A. Long to be Surg. Lt.-Comdrs.

S. J. Atkinson, H. Bradley-Watson, and E. C. Jenet to be Surg. Lts. (D).

### ROYAL NAVAL VOLUNTEER RESERVE

Surg. Capt. J. B. Ronaldson, V.D., K.H.P., to *Pembroke* for R.N.B.

Surg. Lt.-Comdr. A. H. Shelswell to *Drake* for R.N.B.

Surg. Lt. F. W. Baskerville to *Vimy*.

### ROYAL ARMY MEDICAL CORPS

Lt.-Col. C. Scaife retires on ret. pay.

Maj. S. J. A. H. Walshe, D.S.O., to be Lt.-Col.

Temp. Capt. N. W. Walmsley relinquishes his commn. and retains the rank of Capt. (Substituted for notification in the *Gazette* of Dec. 11th, 1918.)

Short Serv. Commissions: Lt. R. Phillipson to be Capt., and J. A. MacDougall, J. C. A. Marchand, and K. H. Foster to be Lts. (on prob.).

### REGULAR ARMY RESERVE OF OFFICERS

Lt.-Col. J. E. M. Boyd, M.C., and Maj. D. de C. O'Grady, D.S.O., having attained the age limit of liability to recall, cease to belong to the Res. of Off.

### ARMY DENTAL CORPS

Cpts. to be Maj. : C. E. Day and W. McAndrew.

Short Service Commissions: Lts. (on prob.) confirmed in their rank: C. W. Upton, J. H. Sherwen, B. E. French, W. F. O'Carroll, R. J. Godfrey, R. Edwards, and A. F. Town.

### TERRITORIAL ARMY

Capt. D. H. Clarke having attained the age limit relinquishes his commn. and retains his rank.

General List: Capt. M. L. Sutcliffe to be Maj.; B. B. Hosford (late Cadet, Highgate Sch. Contgt., Jun. Div., O.T.C.) to be Lt.; and Lt. J. W. E. Webster to be Capt.

### ROYAL AIR FORCE

Flying Offrs. R. C. O'Grady and E. W. R. Fairley to Medical Training Depôt, Halton, on appointment to short service commissions.

*Dental Branch.*—Flying Offr. S. Hill to Home Aircraft Depôt, Henlow.

### AUXILIARY AIR FORCE

T. McM. Boyle is granted a commission as Flying Officer, No. 609 (West Riding) (Bomber) Squadron.

### INDIAN MEDICAL SERVICE

Majs. to be Lt.-Cols.: G. A. Khan, H. H. Elliot, M.B.E., M.C., and D. Clyde.

The undermentioned officers have vacated apts. in India:—

*A.D.M.S.*: Col. N. Low, D.S.O., O.B.E., *V.H.S.*, Brit. Serv.

*D.A.D.P.*: Maj. F. G. A. Smyth, R.A.M.C.

*D.A.D.H.*: Maj. D. G. Chevne, O.B.E., M.C., R.A.M.C.

The undermentioned apts. have been made in India:—

*D.A.D.P.*: Lt.-Col. J. B. A. Wigmore, R.A.M.C.

*D.A.D.H.*: Capt. K. F. Alford, I.M.S.

The undermentioned officers have assumed new appointments in India: Col. W. E. R. Williams, I.M.S., O.B.E., as Assistant Director of Medical Services, Lucknow District; Lt.-Col. H. G. Winter, M.C., R.A.M.C., to Rawalpindi District staff; and Lt.-Col. R. B. Price, D.S.O., R.A.M.C., to Southern Command Headquarters.

Lt. (on prob.) W. J. Young is secd. while holding an aapt. at St. Bartholomew's Hospital, London.

Capt. J. N. Vasudeva relinquishes his temp. commn.

The grant of the rank of Capt. to Capt. Antonelli Saldanha is cancelled.

*Indian Medical Department.*—Lts. (Sen. Asst. Surgs.) to be Cpts. (Sen. Asst. Surgs.): H. A. Young, G. R. Aitkins, A. W. Hazle, F. B. A. Braganza, C. Lobo, E. J. Creais, and J. W. Traynor.

Asst. Surgs. (1st Cl.) to be Lts. (Sen. Asst. Surgs.): R. L. Dunn, W. A. Beer, E. A. Eates, G. U. Oakley, J. J. F. Dunn, A. J. Raphael, C. W. E. Frederick, and C. W. E. Peters.

Majs. (Sen. Asst. Surgs.) L. A. Francis and G. V. Aitkins to retire.

### COLONIAL MEDICAL SERVICE

Dr. D. M. Blomfield and Dr. B. P. Harris have been appointed Medical Officers, Kenya.

H. A. Gilkes, M.C., M.D. (Medical Officer, Northern Rhodesia), becomes Deputy Director of Medical Services, Trinidad.

**NEW END HOSPITAL, HAMPSTEAD.**—The hospitals and medical services committee have submitted to the London County Council four schemes for the improvement of the Council's hospitals. One of the schemes is the erection of a new nurses' home at New End Hospital and the adaptation of an existing building for staff accommodation at a total cost of some £43,500.

**ROYAL EAST SUSSEX HOSPITAL.**—Improvement of the hospital services of the country as part of a memorial to King George was stressed at the annual meeting of the governors of this hospital at Hastings on June 3rd. This institution has been greatly extended in recent years, and when the new theatres and consulting-rooms have been finished, 17 private wards are to be provided for which an appeal will be made. The ninety-seventh annual report gave the number of in-patients during the year as 1805, and the number of out-patients, including casualties, as 12,288, with a total of 74,989 attendances. Road casualties accounted for 96 cases. These involved a cost to the hospital of £889 but only £269 was received in return. There was an excess of expenditure over income of £3860.

## SCOTLAND

(FROM OUR OWN CORRESPONDENT)

## EMBOLISM IN THE LIMBS

Sir Thomas Lewis, F.R.S., delivered the George Alexander Gibson lectures of the Royal College of Physicians of Edinburgh last Monday and Tuesday. His title was Symptoms and Signs of Embolism in the Limbs with Special Reference to Pain. He began by describing the changes which develop in a limb after complete occlusion of the blood-supply with a tourniquet. The limb immediately becomes slightly pale; then a stage of cyanosis develops; and this in turn is followed by reappearance of pallor, which increases. The temperature of the limb falls slowly. If the muscles of the limb are kept at rest there is little or no pain; but if they are exercised, severe pain develops in those that are being used. This pain is due to an accumulation of products of metabolism and disappears in two or three seconds if the circulation is re-established. The blood which restores the circulation must be oxygenated if it is to bring relief. When the limb is kept at rest after occlusion of the blood-supply the first disturbance noticed is that there is some loss of the sense of touch at the finger-tips. This analgesia slowly spreads up the limb from the periphery, at the rate of about 5 cm. per minute. True anaesthesia to light touch develops in the same way, and with it position-sense becomes lost. Muscular power disappears also at this stage. In the upper extremity the small muscles of the hand are first affected; the extensors of the wrist then become weak, and finally the flexors lose power. The ability to appreciate pain and temperature is lost at a later stage. Examination of limbs that have been amputated shows that the pilomotor response is preserved even longer. Sir Thomas Lewis has been able to prove that the effect on the nerves is caused neither by an effect on the end-organs, nor by pressure on the nerve, but by loss of the blood-supply to the nerve. The longest nerves to the ends of the extremities are the most vulnerable, as they also appear to be in cases of peripheral neuritis.

In his second lecture Sir Thomas discussed the cause of the pain which occurs in clinical cases of embolism of the main arteries of the limbs. He explained that the theory commonly accepted was that the pain arises at the moment the vessel is blocked and is due to some local effect on the wall of the artery. This explanation, he believes, cannot be accepted. Numbness and paralysis of the affected limb are often present, it is observed, by the time pain appears, and the site at which the pain is felt is often distal to the position of the embolus. Obstruction of the abdominal aorta, for example, first causes coldness and numbness in the legs and later paralysis and pain felt in the legs, not in the abdomen. Re-establishment of the circulation by operative removal of an embolus at once relieves pain in the limb just as it was relieved, in the experiments, by removal of the tourniquet. The lecturer referred to a case in which an embolus was dislodged from the axillary artery and settled at the lower end of the brachial artery. This event gave complete relief from pain in the arm, though the radial pulse did not return. The blockage of a blood-vessel in the brain or lungs causes no pain, but if a vessel is blocked in a muscular organ, such as the heart or gut, pain is a striking feature of the disturbance

produced. Sir Thomas Lewis concluded, therefore, that the pain caused by embolism of a large artery to a limb develops at an interval after the blockage, and is always associated with ischaemia of the tissues of the limb. The tissue primarily concerned in the production of this pain is, in all probability, the muscles.

## A NEW DERMATOLOGICAL DEPARTMENT

On June 5th Sir Norman Walker opened the new dermatological and venereal diseases department of the Edinburgh Royal Infirmary. The building, which has cost £40,000, has five floors and a basement. The venereal diseases department occupies the lower three floors, while the third and fourth floor form the skin department. Included in the building is provision for 38 in-patients in the venereal diseases section and 46 in-patients in the skin diseases section. Sir Norman Walker said that John Hughes Bennett, who became professor of physiology in 1848, was the first to teach dermatology in Edinburgh. Beds were first set aside for skin disease in the Infirmary in 1891 and the opening of the new eye department in 1905 enabled cases of skin diseases to be admitted to Ward 2. He considered that the new department was the best in the country. Besides the 46 beds available, there are also 90 for diseases of the skin at the Western General Hospital.

## PARIS

(FROM OUR OWN CORRESPONDENT)

## OUTBREAKS OF PINK DISEASE

A RECENT communication by Dr. Rocaz of Bordeaux to the French Academy of Medicine seems to indicate that infantile acrodynia has lately been quite common in the South West of France. Since he reported his first case in 1926 he has observed 68 similar cases himself, and has been informed of 90 others observed by colleagues about whose diagnoses there could be no doubt. If to these 158 cases be added other known cases that Dr. Rocaz has been unable to check and the doubtless numerous cases escaping recognition, the total must run into several hundreds. The geographical distribution suggests that there are several more or less dense centres of this disease, in each of which some 20 to 30 cases have been observed. Other minor centres have been responsible for some 10 cases each. The distribution of the disease would seem to correspond to that of other diseases conveyed by carriers; and in two of the main centres, infantile acrodynia seemed to follow the course of important waterways. Most of the children were aged 1-3 years, and there were few cases above the age of 6. The sexes were equally involved, and the distribution of the cases throughout the different seasons of the year was most irregular. It may perhaps be significant that the centres in which this disease was most common were also those which have suffered much from other neurotropic diseases such as encephalitis and poliomyelitis. The occurrence of more than one case in the same family suggested infection; in one family, a brother and a sister developed typical infantile acrodynia at the same time. In another family one child developed and recovered from acrodynia that overtook another child 20 months later, born in the interval. In a third family, a child developed the disease 3 months after having been in contact with a cousin who was suffering from it.

In the presence of similar events recorded by other observers, Dr. Rocaz is of the opinion that this cannot be explained away as a mere coincidence.

#### PARAMEDICAL ASPECTS OF HANDWRITING

Dr. Camille Streletski has just published a book entitled "Précis de Graphologie Pratique" (Paris, 1936). Its 381 pages contain some 500 specimens of handwriting whose most characteristic features and "true inwardness," as Ibsen used to call it, are commented on by the author in an objective and critical spirit. The investigations of Charles Richet and others have done much to rehabilitate graphology as a science, rather than a game with which to amuse cynics in a court of law. Dr. Streletski's contribution to the subject is as serious as it can be, and in addi-

tion to many original observations, his book contains much evidence of a careful study of the work of his predecessors. Considerable space is devoted to grapho-pathology, a subject in which neurologists and psychiatrists may be expected to be particularly interested. One of the most arresting chapters is entitled "Le film graphologique." Here the author traces the modifications imposed on the handwriting of one and the same person by internal and external changes as he grows older; and one of the most notable subjects chosen for this very, very slow motion film is Dr. Alexandre Guéniot, specimens of whose handwriting from the age of 25 to that of 100 are reproduced. In the course of this work, the author traces the influence of disease and other factors, internal and external, on the handwriting.

## PARLIAMENTARY INTELLIGENCE

### NOTES ON CURRENT TOPICS

#### Reassembly after Whitsuntide

THE House of Commons reassembled on Tuesday, June 9th, after the Whitsuntide recess.

#### Importation of Scientific Apparatus

On June 9th, in the House of Commons, the Finance Bill was considered in Committee. On Clause 5 (which continues Part I. of the Safeguarding of Industries Act, 1921, for a further period of ten years from August 19th, 1936) Mr. THURTLÉ moved an amendment to the subsection which provides for the importation of certain scientific apparatus free of duty provided that the Board of Trade are satisfied that such goods are not likely to be made in this country within a reasonable time, or in sufficient quantities. The amendment provided that the Board of Trade must also be satisfied that such goods are not likely to be available in this country "at a reasonable price."—Mr. G. GRIFFITHS, who seconded the amendment, said that hardship was caused to diabetic patients by the 33½ per cent. duty on hypodermic needles.—Dr. BURGIN, Parliamentary Secretary to the Board of Trade, in reply, said that the section did not apply to hypodermic needles, but was to enable high-priced scientific instruments to be brought into the country free of duty. In the case of such instruments, which would probably be ordered singly, he questioned whether it was possible to define "a reasonable price."—Sir FRANCIS ACLAND said that until a few months ago a first-rate British hypodermic needle made of rustless steel could not be obtained, and if the needle were not rustless the expense of obtaining fresh needles was considerable. There were now two sorts of British needle. We had beaten the foreign needle on merits, and he could not believe that the British manufacturers, having succeeded in making first-class goods, would wish to rely on a high duty.—The amendment was negatived by 192 votes to 131.

### HOUSE OF COMMONS

TUESDAY, JUNE 9TH

#### Destruction of Human Food

Mr. MATHERS asked the Secretary of State for Scotland whether he would give particulars of any instances brought to his notice during the last 12 months of food of any description fit for human consumption having been destroyed; whether he would state the reasons in each case for the destruction; whether action was taken under his authority before or since the food was destroyed; and whether it was his intention to seek any further powers he might have found necessary to prevent such waste.—Sir GODFREY COLLINS replied: According to the information possessed by the Scottish Departments con-

cerned the position in Scotland for the year ended May 31st, 1936, is as follows: Approximately 1200 tons of herrings and 50 tons of other fish were destroyed at ports in Scotland. These amounts represent less than ¼ per cent. of the total landings in Scotland—namely, 275,000 tons. The principal reasons were that supply was in excess of market demand and that the fish was of poor quality. There was also a small quantity of milk which could not be utilised economically on non-school days. I am not aware of any other instances. I have no authority to take any action in the matter.

Mr. WILSON asked the President of the Board of Trade if he would state the cases brought to his notice in which during the last 12 months food of any description fit for human consumption had been destroyed, and in each case the reason for the destruction; the action taken by the department, either before the destruction or since; and whether it was intended to take further powers to prevent such destruction.—Mr. RUNCIMAN replied: No such cases have been brought to my notice beyond those mentioned by my right hon. friend the Secretary of State for Scotland in the answer he has given to-day, to which I cannot usefully add.

#### Reduction of Working Hours

Mr. TOM SMITH asked the Minister of Labour if he had any further information to give the House regarding his discussions with employers of labour on the question of a reduction of working hours.—Lieut.-Colonel MURHEAD replied: No further meetings have taken place since those referred to in the reply given on May 21st. As a result, however, of my right hon. friend's meeting with representatives of the distributive trade the organisations agreed to appoint representatives with whom the department could consult for the further examination of the position with regard to wages, hours, and working conditions in those trades, and communications have been received from other organisations who wish to be associated with these discussions. As pointed out in the previous reply, the principal effect of the discussions has been to cause closer attention to be given to the question relating to absorption of more workpeople into employment, but my right hon. friend proposes to have a report prepared on the discussions for the information of those interested.

#### Experiments on a Dog

Sir ROBERT GOWER asked the Minister of Agriculture what was the nature of the research work begun in the United States of America and continued in this country on a dog permitted to be quarantined at the Royal Maternity and Women's Hospital, Glasgow, during the past year; by whom such research work was conducted; the time of its duration; and whether any pain or suffering was caused to the dog.—Sir JOHN SIMON, Home Secretary, replied that no experiment had been made on the dog since its arrival in the United Kingdom. As Sir Robert Gower was aware, he had no jurisdiction in regard to experiments performed outside the United Kingdom.

## MEDICAL NEWS

### University of Oxford

On June 6th the degree of D.M. was conferred on J. N. O'Reilly. At a convocation on June 24th it will be proposed to confer the honorary degree of D.Sc. on Dr. E. D. Adrian, F.R.S., fellow of Trinity College, Cambridge, and Foulerton professor of the Royal Society.

### University of London

A university readership in physics is to be established which will be tenable at the Royal Cancer Hospital. The regulations for the academic post-graduate diploma in dietetics have been approved and copies may be had from the academic registrar.

Lord Dawson has been reappointed to the senate as representative of the faculty of medicine, and Prof. T. B. Johnston has been appointed representative of the general medical schools.

Mr. R. Davies-Colley and Mr. C. Jennings Marshall have been appointed as examiners in surgery for this year, and Prof. E. D. Telford and Mr. G. T. Mullally as examiners for the M.S. examination in July to fill the vacancies caused by the resignation of Mr. E. K. Martin and Mr. P. H. Mitchiner.

At recent examinations the following candidates were successful:—

#### THIRD EXAMINATION FOR M.B., B.S.

J. C. B. Bone, Middlesex (*a, b, c*, university medal); E. P. Clarke (*d*), St. Bart.'s; C. J. Cobbe (*a*), St. Thomas's; A. L. Craddock (*a*), London; R. S. Ellis-Brown (*d*), Guy's; Joyce M. George (*c*), King's Coll.; Sholem Glaser (*b*), London; C. A. Lillcrap (*a*), Guy's; Mary H. Robbins (*d*) and Eileen D. M. Wilson (*e*), Roy. Free.

(*a*) distinguished in medicine, (*b*) distinguished in pathology, (*d*) distinguished in surgery, (*e*) distinguished in obstetrics and gynaecology.

Ruth M. Addison, Roy. Free; Charles Anderson, St. Bart.'s; G. A. Armstrong, Westminster; H. R. Arthur, St. Thomas's; R. A. J. Asher, London; Mary Barber, Roy. Free; H. H. F. Barns, Univ. Coll.; H. L. W. Beach, St. Bart.'s; B. E. Blair, St. Thomas's; Kathleen E. Burnell, Roy. Free; Henry Caplin, London; H. B. C. Carter-Locke, St. Thomas's; Anny M. Cusack, Univ. Coll.; Thomas Denness, St. Thomas's; E. W. Dunkley, London; A. G. Edwards and G. J. Evans, Guy's; H. D. Fairman, London; J. E. Giesen, Guy's; R. M. Glass, Westminster; Philip Glazer, King's Coll.; Margaret M. Hanford, Roy. Free; H. R. S. Harley, Guy's; Jack Hartsilver, St. Bart.'s; C. E. W. Hoar, Westminster; C. D. Holdstock, London; K. F. Hulbert and A. C. Jones, Middlesex; W. W. Jones, Guy's; A. C. Kanaar, St. Bart.'s; G. H. W. Keates, Guy's; L. M. Kelly, St. Thomas's; H. M. Kelsey, Guy's; F. B. Kiernander, St. Thomas's; F. J. D. Knights, Middlesex; J. H. Lawrence, Univ. Coll.; W. D. F. Lytle, St. Thomas's; J. McA. McArthur, Guy's; J. R. M. Martin, St. Bart.'s; Elizabeth M. Morgan, Roy. Free; E. G. Murphy, Univ. Coll.; Lucy M. B. Nelson, Roy. Free; R. J. Niven, St. Thomas's; K. L. G. Nobbs, St. Mary's; H. A. Oatley, Univ. Coll.; J. D. Ogilvie and W. A. Oliver, St. Bart.'s; John Pemberton, Univ. Coll.; Marjorie L. Penwill, Dorothy J. Perkins, Lena F. G. Priestman, and Grace E. Reed, Roy. Free; J. C. Roberts, St. Bart.'s; Irene H. Rogers, King's Coll.; Eric Sayle, Guy's; Mary Scott, Roy. Free; D. J. Sheehan, St. Bart.'s; W. E. Springford, Charing Cross; W. J. Stokes, London; C. H. Tanner, Univ. Coll., Cardiff; R. N. Tattersall, Univ. of Leeds; Frank Taylor, Guy's; G. R. Taylor, St. Bart.'s; H. C. Thomas, London; R. C. Tudway and Winifred J. Wadge, Univ. Coll.; Alan Wardale and H. F. West, King's Coll.; and Donald Wilson and C. A. Young, St. Mary's.

### University of Wales

At recent examinations the following candidates were successful in obtaining the tuberculous diseases diploma:—

S. N. Ahmed, Pranartharhihara Arunachalam, S. M. Basu, L. R. Dongrey, E. F. Drum, John Duffy, J. K. Feeney, M. A. Hai, D. V. G. Muthu, B. R. Patel, A. K. Shariff, and M. P. Sinha.

### University of Dublin

Dr. O'Donel Thornley Dodwell Browne has been elected to the King's professorship of midwifery in the School of Physic, Trinity College, Dublin, to fill the vacancy left by the resignation of Dr. T. Henry Wilson. Dr. Browne is a medical graduate of the University of Dublin and a fellow of the Royal College of Physicians of Ireland.

### Cambridge Graduates' Medical Club

The annual dinner of this club will be held at King's College, Cambridge, on Friday, June 26th, at 7.30 p.m. Mr. W. H. C. Romanis, vice-president, will take the chair, and the hon. secretaries may be addressed at 1, Park-square West, London, W. 1.

Prof. Charles Singer will deliver the eleventh Fison lecture in the medical school of Guy's Hospital on Thursday, June 18th, at 5 p.m. He will speak on Magic and Medicine in Early England.

### British Social Hygiene Council

Sir Kingsley Wood, the Minister of Health, is to address the annual meeting of the British Social Hygiene Council in the London School of Hygiene and Tropical Medicine, Keppel-street, at 2.45 p.m. on Wednesday, June 17th. All interested are invited.

### Elizabeth Garrett Anderson Hospital

The centenary of the birth of the founder of this hospital formed the occasion of a special visit by its first president, the Duchess of Kent, following a luncheon in the board room to which Sir Alan Anderson and Dr. Louisa Garrett Anderson were invited. Brief speeches were made by Lady Robertson, chairman of the hospital, and Lady Barrett, M.D., who said that 6000 women doctors were now practising in this country. She drew attention to the value of the work being done by medical women and to the wide range of their activities.

### Nurseries for the Children of the Unemployed

Lord Eustace Percy, M.P., formerly president of the Board of Education, opened the extension of the Save the Children Fund's emergency open-air nursery for children of the unemployed at North Shields on June 10th. The extension makes accommodation available for 80 children, aged two to five, instead of 40 as at present. Plans for an additional nursery for another 80 children at the east end of the town and for a nursery at Hebburn-on-Tyne have been passed by the Board. Progress is also reported in regard to other efforts of the fund in providing these nurseries for the children of the unemployed. In South Wales, the possibility of extending the nursery at Merthyr Tydfil is under consideration; and at Hoxton application has been made to the London County Council for recognition of the nursery as it is the only one of the kind in the neighbourhood. Of the 10 emergency open-air nurseries established by the fund during the past ten years, 9 have been recognised by the Board of Education for grant, and their chief medical officer, in his last annual report, gave special commendation to the fund's work in this realm.

## Vacancies

For further information refer to the advertisement columns

Albert Dock Hospital, Connaught-road, E.—Res. M.O., at rate of £110.

Ashton-under-Lyne.—Res. Surg. O. and H.S., at rate of £200 and £150 respectively.

Battersea General Hospital, Battersea Park, S.W.—H.S. and H.P., at rate of £130 and £120 respectively.

Bedford County Hospital.—First H.S., at rate of £155.

Belfast, Royal Maternity Hospital.—Res. H.S., at rate of £100.

Belgrave Hospital for Children, Clapham-road, S.W.—Second H.P., at rate of £100.

Birmingham City Education Committee.—Asst. School M.O., £500.

Birmingham City, P.H. Dept.—Two Res. Asst. M.O.'s, each £400.

Birmingham Selly Oak Hospital.—Res. Surgeon, £700. Pathologist, £750. Also Radiologist, £800.

Blackburn Royal Infirmary.—Res. H.P., £175.

Bolton Infirmary.—H.S., £125.

Bootle General Hospital.—H.S. or Cns. O., at rate of £150.

Bradford, Royal Eye and Ear Hospital.—H.S., £160.

Brecon County.—Asst. M.O., £500.

Brighton, New Sussex Hospital for Women, Windlesham-road.—H.S., £100.

Brighton, Royal Sussex County Hospital.—Cas. H.S., £120.

Bristol General Hospital.—Two H.P.'s, three H.S.'s, Res. Obstet. O., H.S. to Spec. Depts., at rate of £80. Also Cns. H.S., at rate of £100.

Burton-on-Trent General Infirmary.—H.S., £150.

Cardiff, Llanough Hospital.—Sen. Res. Surg. O., £450.

Chesterfield and North Derbyshire Royal Hospital.—H.S. to Ear, Nose, and Throat Depts., at rate of £150.

City of London Hospital for Diseases of the Heart and Lungs, Victoria Park, E.—Asst. Radiologist.

Colchester, Essex County Hospital.—Asst. H.S., £120.

Connaught Hospital, Walthamstow, E.—H.S., at rate of £100.

Croydon County Borough.—Asst. M.O.H. and Asst. School M.O., £500.

Derby, Derbyshire Royal Infirmary.—Gynaecological H.S. and Emergency Anaesthetist, £150.

Derbyshire Education Committee.—Asst. School M.O., £600.

Doncaster Royal Infirmary.—H.P., at rate of £175.

Dorset County Council.—Clin. Tub. O., £750.

- Dover, Royal Victoria Hospital.**—Res. M.O., £180.  
**Dreadnought Hospital, Greenwich.**—H.P., at rate of £110.  
**Eaking, King Edward Memorial Hospital.**—Sen. Asst. Res. M.O., at rate of £200.  
**Elizabeth Garrett Anderson Hospital, Euston-road, N.W.**—Hon. Asst. Phys.  
**Great Yarmouth General Hospital.**—H.S., at rate of £140.  
**Halifax Royal Infirmary.**—Third H.S., at rate of £150.  
**Hampstead General and N.W. London Hospital, Haverstock Hill, N.W.**—H.S., at rate of £100.  
**Hastings, Royal East Sussex Hospital.**—Jun. H.S. and Temp. H.S., at rate of £150 and £200 respectively.  
**Hospital for Sick Children, Great Ormond-street, W.C.**—Cas. M.O., £175. Also Res. Aural Reg., £150.  
**Hospital of St. John and St. Elizabeth, 60, Grove End-road, N.W.**—Res. H.P., at rate of £100.  
**Huddersfield, St. Luke's Hospital.**—Res. M.O., £200.  
**Hull and Sculcoates Dispensary.**—Res. M.O., £500.  
**Ilford, King George Hospital.**—Hon. Asst. Dermatologist, Cas. O. and Surg. Reg., Res. Med. Reg., each £150. Also two H.S.'s, each £100.  
**Indian Medical Service.**—Commissions.  
**Ipswich, East Suffolk and Ipswich Hospital.**—H.S. to the Asst. Surgeons and H.S. to Senior Surgeon, each £144.  
**Ipsworth, West Middlesex County Hospital.**—Asst. M.O., £400.  
**Kent County Council.**—Asst. for Tuber Administration, £900. Also Asst. for Hospital Administration, £800.  
**Kettering and District General Hospital.**—Second Res. M.O., at rate of £125.  
**Kidderminster and District General Hospital.**—H.S., £150.  
**Leeds University.**—Lecturer in Biochemistry and Lecturer in Physiology, each £500.  
**Lingfield Epileptic Colony.**—Asst. M.O., £300.

## Births, Marriages, and Deaths

### BIRTHS

- CARDELL.**—On June 3rd, at Weymouth-street, W., the wife of J. D. Magor Cardell, F.R.C.S. Eng., of a daughter.  
**JOHNSTON.**—On May 31st, at Edinburgh, the wife of Dr. D. Scott Johnston, Gold Coast, West Africa, of a daughter.  
**JORY.**—On June 3rd, at Hightgate, the wife of Norman Jory, F.R.C.S. Eng., of a daughter.  
**MEYER.**—On June 3rd, at Devonshire-place, the wife of Dr. Peter F. Meyer, of a son.  
**PURSER.**—On May 31st, at Devonshire-place, W., the wife of Dr. J. A. Purser, of a son.  
**RANSOME WALLIS.**—On May 31st, the wife of Dr. R. Ransome Wallis, of Marsden, of a daughter.  
**SCOTT.**—On June 3rd, at Hook, Hampshire, the wife of Dr. Rupert H. Scott, of a son.

### MARRIAGES

- CAIGER-SMITH—GRANGER-EVANS.**—On June 3rd, at St. Peter's, Belsize Park, Oliver Caiger-Smith, M.R.C.S. Eng., to Janet Maxwell Granger-Evans, second daughter of the late John W. Evans, F.R.S., and of Dr. Granger-Evans.  
**KNOWLES—TREEBY.**—On June 3rd, Thomas Knowles, M.D. Edin., late of Christchurch, Hampshire, to Janet, widow of Alfred Treeby, J.P., of Whitehayes, Christchurch.  
**MAXWELL—EVANS.**—On June 4th, at St. Bartholomew the Great, Smithfield, James Maxwell M.D., F.R.C.P. Lond., to Elizabeth Nan Evans.

### DEATHS

- AIRD.**—On June 7th, at Hove, Thomas Wilson Aird, M.D. Durh., M.R.C.S. Eng., late of Wallington, in his 86th year.  
**COPE.**—On June 5th, Albert Ernest Cope, M.D. Durh., D.P.H., late of Westminster, aged 68.  
**LIVINGSTONE-LEARMONTH.**—On May 30th, at Yenching University, Peiping, Agnes M. Livingstone-Learmonth, C.B.E., M.B. Edin., wife of Dr. Basil L. Livingstone-Learmonth.  
**MANNING.**—On May 30th, at Swindon, Ernest John Manning, M.R.C.S. Eng.  
**MARTIN.**—On June 5th, suddenly, at Cheltenham, John L. Martin, M.B. Edin., formerly of Chelmsford, aged 67.  
**MORRIS.**—On June 2nd, at Cullompton, Devon, Lt.-Col. Charles Reade Monroe Morris, D.S.O., R.A.M.C.  
**POWELL.**—On June 8th, at Wolfcholt, Ilfley, Oxford, Colonel John Powell, M.B., B.Ch., B.A.O. Dub., D.S.O., late R.A.M.C.  
**ROBINSON.**—On June 4th, at Cannington, Bridgewater, George Burton Robinson, M.B. Durh., L.R.C.P. Lond., aged 67.  
**ROBINSON.**—On June 3rd, suddenly, at Colwyn Bay, Frederick William Robinson, M.D. Aberd., F.R.C.S. Eng., formerly of Huddersfield.  
**STEIN.**—On May 31st, at Hampstead, N.W., Dr. Charles Guthrie Stein, M.B. Edin., aged 81.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

## NOTES, COMMENTS, AND ABSTRACTS

## THE LAW OF ABORTION

## Germany

THE German Eugenic Law of July 14th, 1933, which came into force on the first day of 1934, contained a clause (§ 14) prohibiting sterilisation except as carried out under this law (and of course, castration) unless performed by a doctor in accordance with the recognised principles of medical practice in order to avert serious danger to the life or health of the person concerned and with that person's consent. The revised Eugenic Law of June 26th, 1935, applied this prohibition explicitly also to the artificial termination of pregnancy. In order that any doubt about the exact interpretation of the clause might be set at rest the Ministers of the Interior and of Justice issued jointly three weeks later (July 18th) the so-called Fourth Injunction which amplifies and explains this section of the law for the benefit of the medical practitioner whose duty it will be to carry out its provisions. The injunction may be summarised as follows.

## THE FOURTH INJUNCTION

Sterilisation or abortion for medical reasons, i.e., in the interest of the mother's health, must only be carried out if a specially constituted tribunal has pronounced it to be necessary. When urgency is great, abortion is allowed without previous consent, and consent is excused when in operating for disease of the sex organs sterilisation cannot be avoided.

The Minister of the Interior will set up medical courts for the purpose of considering applications for sterilisation or abortion on grounds of health. Each court is to be under the direction of a president appointed by the Minister, who will select the other members, as far as possible in rotation, from a panel of approved medical practitioners. A doctor is not permitted to refuse to serve, but may be excused on urgent grounds (e.g., of health) by the president; if dissatisfied with the latter's decision he has a right of appeal, in the last resort, to the Minister. Only practitioners of Aryan extraction are eligible for the panel. No fee is payable for service, but members are entitled to claim their expenses according to a scale laid down by the Minister. No doctor may adjudicate on a case referred by him to the court—a rule which may be waived at the discretion of the president if it is impossible otherwise to obtain a sufficient number of members. If the president of the court has proposed a case for decision, a deputy must preside in his stead when this case is dealt with.

Each case must be referred to the court by the patient's own doctor, who must be of approved status, i.e., authorised to practise in Germany. Application is in writing on a special form setting forth the grounds on which the petition is based. Petitions for sterilisation or abortion on social grounds will not be entertained, and are forbidden; petitions on eugenic grounds are not to be addressed to the court but directly to the proper medical authority. Both the application itself and the decision of the court must be based on the principles embodied in directions issued by the Minister of the Interior in conformity with the general consensus of medical opinion.

Before any operation for sterilisation or abortion is carried out, the consent of the woman must be obtained. If possible this should be done before the application is submitted to the court. If the woman's mental condition is such that she is incapable of giving consent, it may be given by her legal representative or guardian; or if she has none by a representative nominated for the purpose by the local authority. Consent may be excused only in extreme urgency.

The application is sent by post or brought by the patient to the court and received by the president, who appoints two members of the panel to deal with it. The names of the examiners are communicated to the patient who attends for examination by each independently at an appointed time. To obviate the possibility of collusion, neither examiner must communicate with his colleague or with the patient's own doctor until he has formed his opinion on the case and conveyed it to the president. Judgment is pronounced by the president on the results of these two independent examinations. If they agree he is bound to pronounce accordingly; if they differ he examines the case himself and gives the casting vote, or in case of difficulty he may call in a consultant to assist him. When the court has reached a decision it is communicated by the president to the patient's medical attendant, whose duty it is to inform the patient.

The patient is required to pay a fee, in order to cover the running expenses of the scheme, according to a scale to be fixed by the Minister. Any surplus that may remain after all expenses have been paid will be devoted to medical charities, i.e., the relief of necessitous doctors or their dependants.

Sterilisation or abortion may only be carried out in an institution, public or private, the choice of which is left to the patient. Abortion may be carried out in the patient's home if removal to an institution is likely to endanger her life or seriously injure her health. In general the operation may not be performed by any of the medical men who have adjudicated upon the case, but exceptions to this rule may be made at the discretion of the president. The surgeon shall be chosen by the patient's doctor, and the fees of both shall be settled in the ordinary way by the patient.

The doctor or midwife in attendance (or failing these, any person, not a relation of the patient or member of her household, present at the time) is pledged to notify the public health authority within three days of all cases of spontaneous abortion and premature labour up to the 32nd week of pregnancy. In the case of induced abortions authorised by the special courts, the surgeon performing the operation must also notify the court within three days of the operation. Failure to notify abortion is punishable by a fine.

If abortion and sterilisation are both deemed necessary for medical reasons in the same case, the Minister's wish is that they should be carried out if possible at one and the same time in order to avoid multiplication of operations. Any patient requiring repeated Cæsarean section should, in general, be sterilised at the time of the second operation.

Any person who performs a sterilising operation or induces abortion without proper authorisation shall be punished by imprisonment.

## A TREATISE ON MEDICAL INDICATIONS

One of the most important clauses of the injunction is that which makes the Minister of the Interior responsible for laying down the guiding principles upon which all applications for sterilisation and abortion, as well as the decisions of the medical tribunals, are to be based. The directions of the Minister are to correspond with the accepted principles of medical science, and he has entrusted the task of formulating the medical indications for sterilisation and abortion to the new official body, the *Reichsärztekammer*. The fruits of its labours have now been published in the form of an official handbook,<sup>1</sup> issued under the editorship of Dr. Hans Stadler. This publication, which contains the text of the Fourth Injunction, explanatory notes, and a series of articles covering the whole field of medical

<sup>1</sup> Richtlinien für Schwangerschaftsunterbrechung und Unfruchtbarmachung aus gesundheitlichen Gründen. Munich: J. F. Lehmann. 1936. Pp. 180. RM.3.75.

indications for sterilisation and abortion, is intended to ensure uniformity of practice. It does not deal with the legal aspects of the injunction, which are included in another authorised handbook.<sup>2</sup> Each of the medical sections is written by an expert, and the subjects dealt with, in order, are the toxæmias of pregnancy, cardiac diseases, pulmonary tuberculosis, other medical conditions (renal disease, blood diseases, &c.), gynaecological diseases, mental and nervous diseases, surgical conditions (malignant growths, &c.), diseases of the ear and throat, eye and skin. A section is devoted to the value of radiology in assisting the medical examiner to form an opinion as to the desirability or otherwise of interference. The articles are illustrated by numerous plates and diagrams, and together constitute a clear and useful summary of the present-day views regarding therapeutic abortion and sterilisation. The book is not intended to be final; it is pointed out that in respect of certain conditions (e.g., the toxæmias of pregnancy) opinion has not yet crystallised, and the results of further research and observations must be awaited before dogmatic statements can be made. The door is thus left open for such revision of the work as future advances in knowledge may render necessary.

No instructions are given in this manual as to the technique to be adopted in performing sterilisation or abortion, for this is done in the commentary. An appendix however is added concerning the use of radiation (X rays and radium) for producing sterility. This is expressly forbidden except where the woman is over 38 years of age, where the state of her health renders any operation dangerous, or where other pathological conditions exist for which radiotherapy is the appropriate treatment. These methods of sterilisation may only be carried out by practitioners and in institutions recognised for this purpose by the Minister, who will also determine the scale of fees to be charged. All cases so treated must be followed up and the results reported to the medical authority.

The book is prefaced by a request to all practitioners to assist the authorities in keeping it up to date by reporting their own experiences in practice.

### England

It is a little significant that the German views on therapeutic abortion should have become available just at the same time as the report<sup>3</sup> of the special committee set up by the council of the British Medical Association, at the request of the representative body, to consider the medical aspects of abortion. In this report the term abortion is defined as expulsion of the foetus before the age of viability (28 weeks). Its frequency is difficult to ascertain, but in this country 16 to 20 per cent. of all pregnancies are believed to terminate in abortion, and there is evidence that in the majority of cases it is artificially induced. Abortion contributes largely to the general maternal mortality and morbidity, especially in criminal cases.

### THE LAW FORBIDS ABORTION

The law unequivocally forbids the induction of abortion in any circumstances whatever; it contains no saving clause to justify a medical practitioner in performing therapeutic abortion. On the other hand, the interpretation of the law is less rigid. Lord Riddell, in addressing a joint meeting of the Medico-Legal Society and the section of obstetrics and gynaecology of the Royal Society of Medicine (Jan. 21st, 1917), stated that a practitioner "will not be liable to conviction if he honestly believes that what he does is required to save the mother's life or health." Apart from conviction, however, the present state of the law renders a doctor liable to indictment with its attendant publicity which may prove almost equally

damaging to his professional reputation, and the committee concludes that the whole question needs to be examined with the object of clarifying the doctor's position in relation to the law, which should at least contain an explicit statement of the principles governing justifiable abortion. Further to safeguard the practitioner the committee would like careful consideration to be given to the proposal that abortion must only be carried out with the approval of two independent medical men; in its opinion the acceptance of this proposal would be one of the greatest boons that could be conferred on the medical profession.

### INDICATIONS, MEDICAL AND ECONOMIC

Pregnancy may be artificially terminated either to benefit the mother or to prevent the birth of hereditarily diseased offspring. In the opinion of the committee, the maternal indications are at present not sufficiently well defined, and it suggests that more uniform standards are highly desirable. With this object in view an attempt has been made to formulate the medical indications for terminating pregnancy. It is not suggested that the classification is final, but it is intended to form a basis for further discussion. As regards eugenic abortion, the committee is of opinion that the procedure should be considered when there is reasonable certainty that serious hereditary disease will be transmitted to the child.

Induction of abortion for social and economic reasons, of which poverty is the chief, is widely prevalent, and is associated with a relatively high mortality-rate, owing chiefly to the fact that it is often practised by unskilled persons under surgically unclean conditions, with consequent risk of sepsis. The committee has no doubt that the legalisation of abortion under certain conditions for non-medical reasons would go far to solve the problem of criminal abortion, but admits that this is a matter for consideration by the community as a whole and not by the medical profession alone.

It will be seen that the German and English proposals follow closely similar lines; the working of the German law may be expected to furnish valuable information as to the probable effects of legalising abortion in England.

### Russia

In Russia the law of abortion is tending towards a restriction of the liberty enjoyed during the last 15 years. On May 26th was issued by the Soviet Government the draft of a new law which will prohibit abortion on health grounds, except where the life or health of a woman is endangered by pregnancy. The penalty suggested for illegal abortion is imprisonment up to two years for a medical practitioner, up to three years for an unqualified operator. There would also be a penalty of two years' imprisonment for any person who compels a woman to undergo an operation for abortion. The consenting woman would pay for a first offence by public censure and for a subsequent offence by a fine up to 300 roubles. The Soviet Union Year Book Press Service, to whom we owe this information, says that the measure has not yet become law, as is generally supposed. It is still a draft, presented to the masses for their consideration, to be passed or amended in accordance with the consensus of public opinion. The Service adds: "When the Soviet Government passed a decree in 1920 granting women the right to abortion it was then regarded as a temporary measure, permissible only so long as the then prevailing economic conditions made the upbringing of children difficult. The position is quite otherwise now. With the increasing prosperity, not only of industrial workers, but of the collective farm peasantry, Soviet women have nothing to fear from larger families. Moreover, the practice of abortion has been found to be injurious to their health. Judging by the numerous letters pouring into the Soviet newspapers and the reports of discussions on the measure in factories and on

<sup>2</sup> Gütt, Rüdln, and Ruttko: Kommentar zum Gesetz zur Verhütung erbkranken Nachwuchses. Second edition. 1936. Same publisher. RM.6.

<sup>3</sup> Brit. Med. Jour., April 25th, 1936, Suppl. p. 231.

collective farms, the draft of the new law is being favourably received. A few objections are voiced now and then in the press. Some women argue that the measure is too sweeping, that abortions should not be entirely prohibited, but should be allowed in exceptional cases, such as when a woman engages in a long course of study."

The proposed measure is not confined to the limitation of abortion. It contains a number of proposals designed to protect mothers and children, such as increased grants for maternity, allowances for families of over seven, provision of 43,000 more beds in maternity homes, extension of the kindergarten system, and the tightening up of regulations for divorce and payment of alimony.

#### DIARIES OF LITERARY PATIENTS

In the view of Dr. Macdonald Critchley,<sup>1</sup> the symptomatology of text-books makes dull reading. He prefers the subjective descriptions of men of letters and quotes from "La Doulou," by Alphonse Daudet, who suffered from tabes dorsalis. Daudet's account of his sufferings is macabre in the extreme. He writes of lightning pains as "great tracks of flame slashing and lighting up my carcass. . . . The torment of the spiked boot. Rats with sharpened teeth gnawing my toes." The girdle sensation is described as "The cuirass . . . actual armour, cruelly clasping my loins with steel buckles, and tongues of burning coal, sharp as needles. . . ." Daudet realised that the fear of pain is often worse than the pain itself. "It is bearable and yet I cannot endure it. It is the terror of it. . . ." And the egotism of the sick man is well expressed: "Pain is always fresh for him who suffers it, and banal for the onlookers. All get used to it except I." At Lamalou, in Nérès, where he underwent a cure, he comments with grim humour on his fellow-sufferers. "The professor . . . I see him putting one foot in front of another, as flat as can be, and staggering; on ice." Finally there is his cynical gibe at the profession: "The doctors are building in Lamalou. They have faith—and what black hats!" That vivid notes by a skilled writer bring home to readers the nature of the subjective aspect of diseases is not to be disputed. No one could fail to be moved, for example, by Barbellion's disease. But whether such gruesome stuff contributes materially to our knowledge of any disease is a different matter.

#### A LITHOTOMY INSTRUMENT TABLE

Mr. J. LYLE CAMERON, F.R.C.S. Eng., writes: A lithotomy instrument table has been made for me by Messrs. John Bell and Croyden, London, W., similar in design to the Mayo model. It is constructed like a bedside table, rests on three ball-bearing castors, and is adjustable in height from 24-40 in. to suit the convenience of the surgeon. The tray is 30 in. long and limited to a width of 9 in. so as not to obstruct the surgeon's access to the field of operation when it is placed transversely in front of him. This table is especially designed to facilitate all operations performed in the lithotomy position, such as those on the vulva, vagina, and rectum. Furthermore, it affords a very convenient left hand instrument tray if placed across the patient's chest, behind the anaesthetist's screen, when the Trendelenburg position is employed.

## ADDRESSES AND ORIGINAL ARTICLES

## ENLARGEMENT OF THE HEART\*

BY JOHN PARKINSON, M.D., F.R.C.P. Lond.

PHYSICIAN TO THE CARDIAC DEPARTMENT OF THE LONDON HOSPITAL; PHYSICIAN TO THE NATIONAL HOSPITAL FOR DISEASES OF THE HEART

CLINICAL and post-mortem study in close and happy comradeship has led to the use in practical medicine of those very pathological terms, dilatation and hypertrophy, which we have been considering. Yet it is of doubtful benefit to borrow them for use in the wards, where it must be admitted there is difficulty enough in determining the simple fact of enlargement. So I suggest that the term enlargement is preferable and sufficient. In a general sense, however, it is not now sufficient; for by radiology it becomes our duty and privilege to identify particular enlargement of the component parts of the heart—i.e., its various chambers—and the channels by which it fills and discharges. It used to be sufficient to say that a pulse was irregular, now such a statement would be unhelpful unless we specify what kind of irregularity is present. And so from radiocardiology we must ask for more than a revelation of enlargement. It must be definitive and inform us of its site, its development, and its extent. Some have gone further, and wish to see in the form of the heart under certain conditions, and its type of contraction, a means of judging the "tonic" or "atonic" state of the heart. From this by easy paths even spurious terms such as a "flabby heart" have been coined again for radiological circulation. Radiology must keep within the law; it must be open to correction by anatomy, physiology and pathology, and by well-informed clinical medicine.

Before proceeding to enumerate causes of clinical enlargement, one may draw attention to certain practical points of interest. Apart from X rays, the apex-beat is undoubtedly the most useful and convenient sign despite its limitations being so patent. Although a systolic murmur at the apex does often accompany enlargement (dilatation) and result from it, it is so common and its origin is so mixed that it cannot be reckoned a sign of enlargement. The electrocardiogram is often of considerable value where it gives clear evidence of right or of left preponderance, and a large or bifid auricular (P) wave may focus attention upon the size of the auricles. In cardiac hypertrophy from hypertension, the left ventricle is especially hypertrophied, but the right ventricle is often affected to a certain extent. Unless notice is taken of this gap in our knowledge, an observer with X rays may be biased and tend to visualise his ideas into the cardiac shadow exactly as I fear that preconceived ideas often biased the percussor. It has been a good custom to collect all the signs first and from these to build a structure upon which an unprejudiced diagnosis may be reached; and radiological signs should be enlisted to follow the same rule and not to usurp the function of diagnosis.

Sporadically the idea survives that the heart gets larger and larger as age advances, but in the absence of that common cause for it, hypertension, enlargement is not a necessary accompaniment even of great age.<sup>102</sup> I have a collection of radio-

cardiograms of men over 80 which present no enlargement, though the heart is seen to lie more transversely on the diaphragm than in the average adult despite the fact that the diaphragm is often low (Fig. 12). It is quite possible, as Assmann<sup>3</sup> thinks, that this is due to lengthening of the thoracic aorta forcing down the base of the heart from which it arises.

The pertinent question in these days is not merely whether the heart is enlarged or not, but which part of it is enlarged, for enlargement is localised and characteristic in many and varied cardiac lesions. Further, these localised changes in the particular chambers of the heart can be recognised in their early stages and not merely in those late stages which come too quickly into the domain of the pathologist. Following this plan I propose to discuss enlargement of the left auricle, the left ventricle, the right auricle, the right ventricle, in this order, and to take examples of those diseases which particularly affect the chamber under consideration.

## Left Auricle

The left auricle might, from its anatomical relations, almost be called the posterior auricle, for it lies against the oesophagus and descending aorta which keep it from the spine. The left auricle is not visible from the front, excepting a tiny portion of the left auricular appendage which adheres to the left border just below the pulmonary artery. It is beyond the reach of percussion, but X rays in the right (I) oblique position show it well, and its posterior border is conveniently outlined by barium in the oesophagus. This important method has now come into current use, for after the presystolic murmur it is the most certain sign of mitral stenosis. Some may be tempted, as I have been, too easily to accept a gentle curve of the posterior border as evidence of enlargement of the left auricle; but the normal variations in this curve are sufficient to render care necessary. It is the abruptness of the displacement of the barium stream as well as its degree which is characteristic; and often the barium is held up in triangular form at the upper end of the left auricle before slowly passing this obstruction in a thinner stream (Fig. 13).

It is becoming important to learn what may be the causes, apart from mitral stenosis, of this demonstrable enlargement. In any patient with auricular fibrillation which has lasted long enough, the left auricle may show change in this direction (Fig. 14). In complete heart-block it often looks prominent. Great difficulty sometimes arises where the left ventricle is greatly enlarged and where the left auricle is simply pushed backwards by it. In such a case the barium convexity is often long and pronounced, though not placed so high or displaced so brusquely as with the special auricular enlargement of mitral stenosis.

The recognition of gross (or aneurysmal) dilatation of the left auricle in mitral stenosis has been often reported in recent years and we find it more common than is usually thought. It should be emphasised, however, that among patients with mitral stenosis may be found every grade of left auricular enlargement from that which is doubtful (and then one should say so) to that which has been labelled aneurysmal dilatation. Curiously enough, not only does the left auricle lie posteriorly so that almost nothing of it is seen from the front, but when it enlarges it nearly always enlarges to the *right* so that it begins to appear on the right border of the heart at a little higher level than the right auricle, the border of

\* The second Lumleian lecture for 1936 delivered before the Royal College of Physicians of London on March 19th. The first lecture appeared last week.

which it gradually passes (Fig. 15), if the clinical course happens to extend over years. As you know, the most extreme enlargement allows extension of the left auricle to the right axilla where it has even been tapped as if it were a right pleural effusion (Fig. 16). It possesses clinical features of great interest, such as the moderate symptoms which may accompany a heart so hugely dilated, a clinical contrast with the patient so ill with a comparable ventricular enlargement as from hypertension.

### Left Ventricle

As the left border of the heart when seen from the front is formed by the left ventricle, enlargement is often easy to recognise, and displacements are the

trophy of the heart, chiefly though not exclusively of the left ventricle, but there is also hypertrophy of the media of the muscular arteries, and this should form an integral part of the criteria of enlargement from hypertension.

Coarctation (congenital stenosis) of the aorta is worth remembering as a rare cause for enlargement of the left ventricle, with hypertension affecting only the upper part of the body.<sup>36</sup>

Even where it is most expected as in aortic incompetence or hypertension, one may not assume that radiological evidence of enlargement will invariably be found; such retention of normal size against odds is a cardiac event which may some day be found to possess clinical interest and significance.

FIG. 12.—Normal heart, anterior view. Healthy man aged 93.

FIG. 13.—Mitral stenosis. Teleradiogram, right (I) oblique position. Barium in the oesophagus passes over the aorta (aortic bed) and is then held up by the enlarged left auricle which projects into the posterior mediastinum.

FIG. 14.—Auricular fibrillation without mitral stenosis. Enlargement of left auricle outlined by barium in the oesophagus (continuous line), and greater enlargement six years later (dotted line).

chief source of difficulty and a familiar one. In health, the apparent size of the left ventricle depends much upon the height of the diaphragm. Right ventricular hypertrophy, whether from extreme pulmonary disease or from congenital lesions, can displace the left border of the heart outwards and simulate enlargement of the left ventricle.

The causes of left ventricular enlargement are familiar; aortic stenosis, whether rheumatic or atheromatous, gives a picture very like that of aortic incompetence, though seldom is the heart so large, and with the latter there is more pulsation both in the heart and in the aorta. It may at once be asked whether X rays help in the separation of rheumatic from syphilitic aortic incompetence, the two common varieties of aortic leak. The distinction can only be drawn by establishing a coincident and characteristic change in the aorta, either an aneurysm or such a degree of dilatation or pouching as could not be simulated by the dynamic dilatation of the ascending aorta in free rheumatic aortic incompetence (Figs. 17 and 18). Cardiac enlargement from syphilis, in the absence of aortic incompetence, is a rare occurrence.

The other common cause is hypertension, which even now is scarcely appreciated at its full value as a source of cardiac enlargement. In the absence of valvular disease there is nothing like hypertension for compelling cardiac enlargement. The term cardiovascular hypertrophy was introduced by Turnbull<sup>109</sup> for the anatomical counterpart of clinical hypertension. There is not only hyper-

Cardiac aneurysm has been the subject of numerous pathological reports for generations, and in his well-documented study in 1903, Dr. Donald Hall<sup>45</sup> took the modern view that it is rarely syphilitic, and almost always due to coronary atheroma. Now that coronary thrombosis has become a frequent clinical diagnosis, it would not be surprising if cardiac aneurysm were to follow suit, for X rays make it possible to see the aneurysmal bulge in a fair proportion of cases. As you know, it is the apical portion of the left ventricle which is most often affected, and this lies within our radioscopic vision. Most typical is a localised promontory even to angulation on the left border of the heart seen from in front (Fig. 19). In one such case, however, necropsy showed me that the prominence mistaken for a cardiac aneurysm was, in fact, the apex of the heart lifted by the aneurysm itself which lay upon the diaphragm. In the right (I) oblique position, I have seen an aneurysm fill the anterior lung space at its lower part and prevent the normal illumination of this part of the space even during deep inspiration. It will be apparent that an extensive aneurysm may simulate very closely an ordinary hypertrophy of the left ventricle; and this was so in one patient where necropsy revealed an extensive aneurysm involving the lower half of the left ventricle. Once I saw a line of calcium in this region, almost parallel and just internal to the left border, permitting the diagnosis of calcified aneurysm which was confirmed. The almost constant thrombosis within a cardiac aneurysm brings additional clinical risks.

### The Size of the Heart after Coronary Thrombosis

Coronary thrombosis is so clear a proof of coronary atheroma that it may serve as a basis for studying enlargement in coronary disease.

Hypertension is by far the most frequent and important cause of the enlargement which is often seen. So true is this that even with normal blood pressure at the time of examination, past hypertension should be held responsible for left ventricular enlargement unless aortic stenosis or some other known cause explains it; or there is in the history good evidence to the contrary. But when a patient is known to have had normal blood pressure for years prior to the attack, or when enlargement begins to develop after it (still without raised blood pressure), then the interesting question arises as to whether or not coronary disease itself causes enlargement.

Evidence has been collected that hypertrophy may be produced by interference with the proper blood-supply of the myocardium. If that is so, there is theoretically no reason why the same result should not follow coronary obstruction. Cardiac enlargement is known to occur in experimental<sup>38</sup> and clinical<sup>5</sup> anæmia; in cases where an anomalous coronary artery arises from the coronary sinus<sup>22 13</sup>; and in deficient coronary flow.<sup>100 71</sup>

That coronary disease is actually a cause of hypertrophy has not been conclusively proved. *Experi-*

excluded, and where the hypertrophy was ascribed to coronary disease alone. But their results have been criticised and it does seem likely that hypertension had operated in some of their cases. *Clinical* evidence controlled by X rays is scanty and it is largely negative. Horine and Weiss<sup>51</sup> report 20 cases in which enlargement did not supervene during periods averaging four years after the attack.

In the last few months Dr. J. H. Palmer has investigated and will shortly publish a series of 200 patients who have been under my observation for extended periods following coronary thrombosis and where there were X ray records. The evidence of enlargement has been judged by radioscopy and by inspection of teleradiograms. The average period elapsing between the attack and the last X ray examination was about three years; 40 cases were examined at intervals during more than five years.

Among the whole 200 cases of coronary thrombosis were found 128 (64 per cent.) in which the heart was enlarged. There was every reason to think that hypertension was the predominant or single cause of enlargement in 106 (82·8 per cent.) of these 128 cases. In 4 cases (3·1 per cent.) there were associated but incidental factors which were accepted as causative. In 7 cases (5·5 per cent.) the cause for the cardiac enlargement could not be ascertained, though both factors of hypertension and coronary sclerosis may have been at work.

By process of exclusion we found that coronary

FIG. 15.—Mitral stenosis. Teleradiogram, anterior view. The left border is straight from aortic knuckle to apex from filling out by the pulmonary artery and the conus. The bulge on the right border is caused by enlargement of the left auricle to the right and behind the right auricle.

FIG. 16.—Aneurysmal dilatation of left auricle. Mitral stenosis. Auricular fibrillation. Post-mortem control. Teleradiogram, anterior view. In the right side of the thorax the left auricle extends to the right axilla.

FIG. 17.—Rheumatic aortic incompetence. Teleradiogram, anterior view. The left ventricle is enlarged as shown by extension of the left border of the left and increased convexity of it. The ascending aorta is unduly prominent (dynamic dilatation).

mental evidence is contradictory.<sup>101 107</sup> *Pathological* evidence is complicated by the notorious difficulty of excluding the possibility of hypertension. Nemet and Gross<sup>84</sup> found it difficult to believe that coronary sclerosis is an important factor in the development of hypertrophy, and Bell and Clawson<sup>10</sup> went so far as to state that such a conception is physiologically unsound. Lisa and Ring<sup>72</sup> were unable to estimate the importance of coronary disease as a factor in causing hypertrophy; Nathanson<sup>83</sup> could find no relation between the degree of fibrosis and the size of the heart. Miller and Weiss<sup>80</sup> published a series showing no gross hypertrophy. On the other hand, Bartels and Smith<sup>8</sup> reported 37 cases with necropsy and previously had reported two others<sup>103</sup> in which all known causes of enlargement, including hypertension, were believed to have been satisfactorily

thrombosis was the sole factor in producing enlargement in 4 patients—i.e., 3·1 per cent. Each of these was known to have had normal blood pressure prior to the attack, and hearts of normal size when the attack occurred. To these 4 patients should be added 4 others (3·1 per cent.) in whom cardiac aneurysm was diagnosed by X ray, one confirmed by necropsy. No figures of their blood pressure before the attack are available, but it was not raised subsequent to the attack. A further addition of 3 patients (2·4 per cent.) who showed a bundle branch lesion might be made, for this is fair evidence of coronary disease, and in two it arose after the attack. If in these last three groups the enlargement was directly the result of coronary thrombosis, we have a grand total of 11 (8·6 per cent.) where we believe that cardiac infarction was the single cause of enlargement.

### Right Auricle

The right auricle is as clearly visible from in front as is the left ventricle. Tricuspid stenosis is so very rare compared with mitral stenosis that we do not expect often to see much enlargement of the right auricle. The effects of auricular fibrillation are shown in course of time by enlargement of both auricles. If there is tricuspid incompetence either from valvulitis or more usually from enlargement of the right ventricle late in mitral disease, some enlargement of the right auricle is a natural sequence.<sup>30 50</sup> This is to be seen also in late stages of pulmonary disease, but the rarity of auricular fibrillation in failure from this cause makes right auricular (and also left auricular) enlargement late or little pronounced. In congenital defects of the auricular septum the right auricle is enlarged to an extreme degree, especially where with it there is coexistent mitral stenosis—Lutembacher's disease.<sup>74 78</sup> It is well, where the increased prominence of the right auricle is found, to look for increased breadth of the vascular pedicle from distension of the superior vena cava, which clinically we should expect in association with distended veins in the neck.

It will be agreed that isolated dilatation of the right auricle is most exceptional. For this reason I am fortunate in being able to show records of such a case, thanks to the courtesy of Dr. Cotton. A man

astinum can actually appear as a shadow behind the right auricle and going beyond it (Fig. 21). Once I saw a doubtful shadow in this region which proved to be that rarity a low œsophageal pouch (Fig. 22). This is similar to a figure published by Berg,<sup>11</sup> where the intruding shadow was a para-œsophageal hernia.

### Right Ventricle

There was once much controversy, and a great heresy as Dr. Graham Steell says in his book, about the nature of the pulsation in the second left interspace, for it was thought to be due to pulsation of the left auricle, although it is only the appendix of the left auricle that comes to the front, a part of the chamber least likely to become dilated and often found plugged with clot. The pulsation is now accepted as due to the pulmonary artery and the conus (or infundibulum) of the right ventricle, one or both of these. The conus has acquired a new importance as part of the right ventricle, simply because it becomes radioscopically visible on the left border as the only portion of the right ventricle which can be seen from the front. Fortunately, in addition, the right ventricle forms part of the cardiac outline when the subject is turned well to the right, the left (II) oblique position, about 60°.

The causes of right ventricular enlargement include chronic pulmonary disease, many congenital malformations—e.g., Fallot's tetralogy—and late

FIG. 18.—Syphilitic aortic incompetence. Teleradiogram, anterior view. The left border is rounded and extends to the left (large left ventricle). The ascending aorta is not only prominent but irregular in outline, and on the left the aortic knuckle is large and merges in the descending aorta.

FIG. 19.—Aneurysm of heart. Post-mortem control. Teleradiogram, anterior view. Angulation on left border.

FIG. 20.—Aneurysmal dilatation of right auricle. Post-mortem control. Cause undiscovered. Teleradiogram, anterior view.

of 39 suffered an illness like coronary thrombosis two years before he came to hospital with cardiac dyspnoea, when a most unusual enlargement of the heart was noted (Fig. 20). Necropsy showed absence of valvular disease, and an aneurysmal dilatation of the right auricle, but no evidence of coronary thrombosis affecting the auricular branches.

There are certain simulations of right auricular enlargement, and Bordet<sup>16</sup> points out that enlargement either of the left ventricle or of the right ventricle may displace the right auricle as a whole to the right, and give a false impression of right auricular enlargement. An aneurysm of the ascending aorta may lie so low on the right of the cardiac shadow (even reaching the diaphragm) that it hides the right auricle. More surprising still is the arteriosclerotic aorta which in its tortuous descent in the medi-

stages of congestive failure from almost every cause. In the beri-beri heart, enlargement affects especially the right auricle and right ventricle.

I will expand these remarks on the right ventricle to include some observations which Dr. Clifford Hoyle and I have undertaken in the last two years in the cardiac department of the London Hospital.

### Pulmonary Causes of Right Ventricular Enlargement

#### EMPHYSEMA

When a patient suffers from chronic bronchitis and emphysema, it is often hard to tell to what extent, if any, the heart is secondarily affected and is contributing to his troubles. The symptoms have much in common, dyspnoea being paramount; and

the arts of percussion, palpitation, and auscultation are of little service in deciding the point. Under these difficulties we are driven to search for some newer method of investigating the heart if we believe that judgment on enlargement will be of value. If it were not, then we should have to rely solely upon signs of heart failure, which are less distinctive in a patient often orthopneic from pulmonary disease. Enlargement of the liver with œdema of the legs would naturally settle the question. Still, it would be well for us to be able to recognise that the heart is involved before the patient reaches so late a stage, which in this form of heart failure is seldom less than the terminal stage.

Until recent years the literature on the heart in emphysema, taking a common form of pulmonary

mechanically produces a comparable destruction of a large part of the finer vascular branches in the lungs. However this may be, the agreed essential factor is a raised tension in the pulmonary circuit—a hypertension of the lesser circulation comparable with the hypertension of the greater circulation which is so mighty a cause of left ventricular enlargement.

The frequency of cardiac enlargement in emphysema is far greater than the incidence of heart failure from this cause might lead us to expect. There is no doubt that associated cardiac disease, hypertension especially, is not only often combined but is also the more powerful cause of failure and death. Many are of an age when they are liable to myocardial disease, and electrocardiographic evidence of

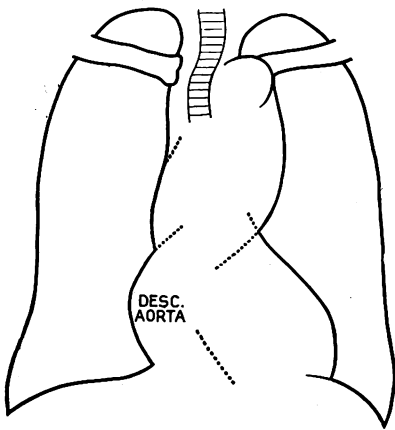

FIG. 21.—Arteriosclerosis. Tortuous aorta, forming right border of "cardiac" outline (from teleradiogram, anterior view).

FIG. 22.—[Esophageal] pouch (lower end), simulating enlargement of right auricle. Teleradiogram, anterior view. The shadow on the right was identified after ingestion of barium.

FIG. 23.—Emphysema. Enlarged conus of right ventricle. Teleradiogram, right (l) oblique position.

disease, consisted chiefly of pathological reports describing enlargement of the right chambers, and later of the pulmonary artery. The differences of opinion have centred upon the relative frequency of cardiac involvement, the unilateral or bilateral effect upon the heart chambers, and the possibilities of cardiac failure directly due to right-sided enlargement from this and similar lung disease. The ultimate cause for pulmonary hypertension and cardiac change may be one or more of three recognised histological changes. First, destruction of the lung tissue with the finer pulmonary vessels, which is inseparable from emphysema and characteristic of it. Secondly, sclerosis of the finer branches of the pulmonary artery and later of its stem. Thirdly, endarteritis of the pulmonary arteries. Though no one doubts that these last two are occasionally reflected in the right ventricle, neither has been often enough reported on good authority to account for the large proportion of cases of emphysema which do show evidence of right ventricular enlargement or pulmonary artery dilatation, or of both. For this reason I cannot help thinking that the over-distension and eventual destruction of the alveoli and larger elements of lung tissue with their fine vascular content is amply sufficient to embarrass the right ventricle and to provoke a hypertrophic response. Supporting evidence is the fact that right heart changes are chiefly or only seen in chronic pulmonary tuberculosis when there is extensive fibrosis which

it may be present; some die of pulmonary complications proper. Though heart failure from pure emphysema is uncommon, no pathologist seems to doubt that some degree of enlargement of the heart in emphysema is common.

*Radiological Changes in Emphysema.*—Many writers have thought that, far from being enlarged, the heart is smaller than the normal. The small cardiac shadow (the genesis of this belief) is due to the low position of the diaphragm with consequent swinging of the heart towards the middle line together with some rotation of the heart on its long axis in a counter-clockwise direction.<sup>96</sup> Such is the drop-like or ribbon-like heart in its simplest form, though it is occasionally seen in a normal person of slight build and long thorax as well as in a small proportion of tuberculous and emphysematous patients.

Dietlen was one of the first to describe the heart changes in emphysema,<sup>28 29</sup> mentioning a blunting of the right cardiophrenic angle due to participation of the right ventricle in the right border, prominence of the pulmonary artery and of the conus (infundibulum) of the right ventricle. He knew that when the left ventricle was normal there would not necessarily be an increase in the apparent size of the heart shadow. Partly for this reason and partly influenced by the frequency of associated cardiovascular lesions, a number of observers have found difficulty in discovering enlargement among emphysematous subjects.<sup>2 62 89</sup> Some previously doubtful

now admit that the heart is affected in the majority of patients with emphysema.<sup>63</sup> Even Vaquez and Bordet<sup>110</sup> are surprised at the infrequency of change even in very chronic cases, and when present found it was of the "sabot" type or at least there was an increased transverse diameter from the enlarged right ventricle. Even more advanced, and each with failure, were the group of cases described so ably by Lutembacher under the title of "Terminal tricuspid syndrome in chronic lesions of the lung."<sup>73</sup> Here also the heart was characterised by gross enlargement of the right ventricle and prominence of the pulmonary arc. Assmann<sup>3</sup> affirms that fairly regularly a hypertrophy of the right ventricle is present in emphysema.

Dr. Clifford Hoyle and I have been interested in

heart were rarely seen. It is not that cardiac enlargement is absent, as some have supposed, but that the signs of right ventricular enlargement are different and elusive, being not nearly so patent as the signs of left ventricular enlargement to which ordinary physical signs are so largely directed. If in addition the left ventricle is enlarged, it is nearly always explained by hypertension past or present, or else by a myocardial factor.

Right ventricular enlargement is most commonly shown by undue prominence of its conus as seen from the front or far better as seen in the right oblique (I) position (Fig. 23). The pathological and experimental evidence from Kirch, already discussed, points to the conus or far end of the outflow tract of the right ventricle as the seat of the first change

FIG. 24.—Emphysema. Enlarged right ventricle. Teleradiogram, left (II) oblique position. Note also dense left pulmonary artery crossing below arch of aorta.

FIG. 25.—Emphysema. Prominence of pulmonary artery (middle arc), and prominence of both its branches. Teleradiogram, anterior view. Post-mortem control.

FIG. 26.—Goitre. Auricular fibrillation. General enlargement of the heart (ham-shaped). Teleradiogram, anterior view.

this subject, and have collected some evidence during the last two years of the changes in the size and shape of the heart in emphysema. We have had at our disposal about 75 cases where emphysema was undoubted, though we like others found repeatedly that the coexistence of hypertension and of other cardiovascular disease complicated the inquiry. It is admitted that pure cases of so-called emphysema heart are not frequent, and that failure from this single cause is infrequent. On the other hand, it was established that slight changes in the size or form of the heart were present in a large proportion, perhaps in half the cases of unselected and consecutive emphysema. Some of the simpler current measurements of the heart's size were tried, but they proved inapplicable to right ventricular enlargement which was what we sought to measure. The cardiothoracic ratio is invalidated by the excessive width of the chest in emphysema. The simple transverse diameter was found to be so little affected that it was useless as a measure of the right ventricular enlargement which was demonstrable in the conal prominence and other signs about to be described. Recently Binhold<sup>12</sup> has applied Kahlstorf's method<sup>53</sup> of volumetric measurement which is based not only on the surface area of the orthodiagram but also on the depth of the heart, to a series of emphysematous patients and found that the heart volume lay at the upper limit of normal and sometimes exceeded it.

The small drop-like heart and the large "sabot"

when resistance rises in the pulmonary circulation. The right ventricle lengthens rather than widens, and this is often missed if one looks for a widening of the transverse diameter of the heart from the front in emphysema.<sup>64 85 120</sup>

This prominence of the conus is commoner and more pronounced than enlargement of the body of the right ventricle. The indications of the latter are said to be a blunting of the right cardiophrenic angle from the appearance there of a right ventricular element in addition to the right auricle.<sup>29 81</sup> This is hardly established, but workers with kymography will probably settle the question in time. Certain it is that the body of the right ventricle is better seen with the subject in the left (II) oblique position, rotated to about 60°, when the lower right (or ventral) border of the heart is formed by that chamber (Fig. 24). At a smaller angle of rotation, as confirmed recently by valuable researches by Laubry and his co-workers,<sup>66</sup> the right auricle forms the limit of the cardiac shadow. Though there is much normal variation in this large curve, in emphysema it is often so large and rounded that no doubt can be felt that it represents enlargement of the body of the right ventricle.

The next radiological feature of the emphysema heart is the prominence of the pulmonary artery in the anterior view (Fig. 25) and the dilatation of its branches. The large drooping branches of the pulmonary artery as seen from the front have been said to look like a moustache. There is both increased

width and increased density of these shadows which need no longer be confounded with non-vascular or bronchial changes. In the left (II) oblique, the left pulmonary artery can easily be followed in a normal film, but in emphysema its size and density are excessive (Fig. 24).

In clinical medicine there is no better example of pure right ventricular hypertrophy than that which occurs in an advanced and uncomplicated case of pulmonary emphysema. In pulmonary hypertension from emphysema there is not the special involvement of the left auricle which modifies the picture so greatly in mitral stenosis, nor the presence of auricular fibrillation which in itself is quite capable of altering the size and form of the auricles at least, and maybe in time of the ventricles.

We leave our study of the heart in emphysema with the feeling that the analogy between pulmonary hypertension in its effect upon the right ventricle, and arterial hypertension in its effect upon the left ventricle, is a correct and considerable one. The emphysematous patient is liable to broncho-pneumonia and other such risks, and he is old enough to have some degree of coronary disease as well; but he is spared the disadvantages and the earlier failure of fibrillation. Compared with him, the hypertensive patient has his cerebral risks, and he is still more often the subject of coronary disease. As regards fibrillation, though this is not the rule with hypertension even in its final stage, it is met more commonly than in pulmonary heart disease. Sclerosis of the pulmonary artery and its branches is the appropriate result or concomitant of pulmonary hypertension, and greatly modifies the occasional case, though not nearly so often as general and local arteriosclerosis alters the course and consequences of arterial hypertension.

Although I have spoken freely of right ventricular in contrast to left ventricular enlargement, when it comes to failure I feel that while the separation into right heart failure and left heart failure will help us to a better understanding of the factors in operation, it will not alter the fact that patients actually in a state of congestive heart failure are very much alike. Indeed, I think that there is more difference between a congestive failure with fibrillation and one without, than there is between what is distinguished as right heart failure and left heart failure.

#### TUBERCULOSIS

In chronic pulmonary tuberculosis the heart often looks small though it is not smaller than normal except with bodily wasting. The idea that its smallness is a hypoplasia which disposes to tubercle is not now strongly held. Where there is much fibrosis, the changes in the right ventricle and pulmonary artery described under emphysema will sometimes be found. As a factor contributing to the symptoms, the displacement and distortion of the heart should be taken into account.<sup>23 20</sup> In a series of 120 cases of pulmonary tuberculosis, Hirsch<sup>46</sup> found right ventricular hypertrophy in 35 per cent., and it appeared to be correlated with the extent of pleural and pulmonary fibrosis. There are also good pathological studies by Brown<sup>19</sup> and by Mayer.<sup>76</sup> Early orthodiagraphic measurements were made by Achelis<sup>1</sup> and later X ray studies have been made by King and Hansen.<sup>57</sup> An extensive thesis on the subject with a good bibliography and references to the X ray appearances has been written by Godel.<sup>43</sup>

A general conclusion would be that the heart in pulmonary tuberculosis is enlarged only from other associated causes, or that it is a right-sided enlargement from fibrotic or emphysematous change in the

lung tissue involving the pulmonary circuit. The fact should be considered by those who wish to see in toxæmia, whether general or even trivial and focal, an excuse for what is really an ill-considered or a fanciful diagnosis of "a slightly enlarged heart" or "a slightly dilated heart." The heart in advanced tuberculosis after years of tachycardia and mixed infections of all kinds with pyrexia presents no enlargement. Examples of heart failure, even under these conditions, are the rarest.

#### PNEUMOCOONIOSIS

Pulmonary heart disease is not rare in pneumoconiosis, and Dyson<sup>31</sup> found evidence of it in 18 of 127 cases where there was reason to expect pulmonary obstruction. He has also given a description of the radiological changes in 5 cases<sup>32</sup> which are comparable with those which Hoyle and I have found in emphysema.

#### Spinal and Thoracic Deformities and their Effect upon the Heart Size

Apart from the slight and the great displacement produced by scoliosis and kyphoscoliosis, these deformities have long been known to be capable of causing actual cardiac enlargement. Historical references have been quoted in the papers by Boas,<sup>15</sup> Edeiken,<sup>33</sup> and Rösler.<sup>32</sup> Most observers have stressed the involvement of the right side of the heart, and believe this follows obstruction in the pulmonary circulation from emphysema or from the considerable compression of the lung in the deformed thorax (hunchback's heart). Needless to say, lung complications are frequent; and there is reason for thinking that the effect upon the lungs is essentially more important than any primary effect upon the heart, which is difficult to understand unless there is actual compression of it. None the less, some of the largest hearts on record have been described and presumably correctly interpreted in this condition, though it is hard to believe they are anything but rare if kyphoscoliosis is the only cause in operation. As would be anticipated, a variety of peculiar patterns have followed the extremes of angular kyphosis of tuberculous origin, such as the case of acute angulation of the aortic arch recorded by Carey Coombs,<sup>34</sup> and cases described by Finley.<sup>37</sup>

The radiological evidence of enlargement in such a misshapen chest has to be accepted with great reserve, and anyway it has less importance if we admit how rarely these heart conditions are seen nowadays either clinically or pathologically. The radiology of the heart in thoracic deformities has especially been studied by Rösler.<sup>32</sup> Incidentally, just as a curvature to the right near the stem of the heart may superficially resemble an aneurysm, so may the rarer curve to the left simulate a prominence of the pulmonary artery. The funnel chest has some interest, though even when extreme it may not be accompanied by any cardiac or pulmonary disorder.<sup>34</sup> It is a potent cause of heart displacement to the left, for there may even be no room for the heart between the depressed sternum and the spine. In modern times extreme angular deformity from tubercle, which used to provide curious heart affections, is happily seldom seen.

#### Pulmonary Artery

Although anatomically not a chamber of the heart, the stem of the pulmonary artery is so distinct and important a part of the cardiac outline that it must at least be mentioned in considering heart size. Besides, the branches of the pulmonary artery are seen to such advantage and profit in so many cardiac

diseases that they merit full attention. No one can deny that the entry of the pulmonary artery into an important place in clinical cardiology in recent years has been as much due to radiology as to pathology.

The pulmonary arc may be simulated in displacement of the heart to the left by any cause, including localised pleural adhesions. Once, Dr. Bedford and I found a pulsating swelling of the middle arc and at first thought it to be an aneurysm of the pulmonary artery. Further X ray examination made us revise our opinion and later at necropsy it was found to be an aneurysm of the ascending aorta which had invaded the natural territory of the pulmonary artery and eventually perforated into the conus.

Of congenital malformations with clinical interest should be mentioned patent ductus arteriosus and auricular and ventricular septal defects. Of acquired lesions, there is simple distension of the pulmonary artery in mitral stenosis, congestive failure, and (sometimes early) the goitre heart. Disease of the pulmonary artery itself include atheroma, both senile and secondary to mitral stenosis or congenital defects, and the rare syphilitic lesion. When the finer branches of the pulmonary artery are affected, or at least when there is pulmonary hypertension, the pulmonary artery enlarges in chronic pulmonary disease, and if the lesion is syphilitic, Ayerza's disease in its most typical form may result. An aneurysmal dilatation of the pulmonary artery is far more often associated with a congenital defect than with syphilis.†

#### Enlargement of the Whole Heart

This is well seen in combined lesions such as mitral stenosis with aortic incompetence or stenosis, or less often with incidental hypertension. In the severest forms of rheumatic carditis we have seen that the heart may enlarge as a whole. In the advanced stages of congestive heart failure from whatever cause there is general enlargement of all chambers; and incidentally the lack of visible pulsation in the heart under these circumstances may be striking.

The heart affected by goitre is sometimes found enlarged, though years may pass before it is demonstrable. Whenever auricular fibrillation supervenes, as so often it does, enlargement can be expected. Some years ago Dr. Cookson and I<sup>87</sup> published a series of observations on the size and shape of the heart in goitre and gave examples of the early change characterised by prominence of the pulmonary artery; of the middle stage with moderate enlargement of the whole heart, supposed to be ham-shaped (Fig. 26); and of the final stages with congestive heart failure with further enlargement and prominent signs of pulmonary congestion. Later, Dr. Hoyle and I drew attention to a frequent association we termed thyrotoxic hypertension,<sup>88</sup> which naturally modifies the radiological picture. Since then the pathological evidence about enlargement from this cause has been strengthened<sup>89</sup> and careful cardiometric observations in life have been carried out.<sup>75</sup> No longer need other cardiac causes be requisitioned to explain the enlargement which can and often does result from thyrotoxicosis alone.

If time permitted I would refer to the general enlargement of the heart which follows an arteriovenous aneurysm and which may largely disappear after operation. The considerable enlargement which sometimes occurs in myxœdema has often been

reported, recently by Campbell and Suzman,<sup>11</sup> and also occasionally in severe and chronic anæmia where the cardiac enlargement resembles that seen with goitre.

When a considerable enlargement of the heart is encountered and no single cause or combination of causes seems sufficient to account for it, we should consider a past hypertension, or else a latent mitral stenosis for the characteristic murmur is sometimes lacking over a long period. Similarly, an unusual combination of congenital defects may account for such a difficult problem. Occasionally a tumour mass or a collection of fluid such as a mediastinal pleural effusion or a pericardial cyst will give difficulty, or even an unusual extension of an aortic aneurysm. There is such a condition as acute isolated myocarditis,<sup>97 99</sup> and cases of "idiopathic" hypertrophy are published from time to time,<sup>113 68</sup> most often in children.<sup>65</sup>

#### Prognosis and Cardiac Enlargement

There is much truth in the statement that the larger the heart the worse the prognosis, though it could seldom be applied strictly to an individual patient. It assumes, often correctly, that enlargement is a fair index of the severity of the myocardial lesion and of the liability to failure. We cannot expect much from either time or treatment when the left ventricle is gross. Auricular enlargement is borne better and longer than ventricular. Increase in size being almost inseparable from particular lesions, in these it may also be said that relative to the lesion the smaller the heart the better the prognosis, for smallness is a fair measure of comparative myocardial health. Grant,<sup>44</sup> from his valuable analysis of after-histories for ten years of 1000 men suffering from heart disease, concluded that the grade of enlargement, with that of failure, provides the most satisfactory basis for prognosis.

Another statement might be made, with reserve, that the heart once enlarged is always enlarged. It is undoubtedly true of the average patient with valvular disease or hypertension, for it is nearly always a slow but steady development of enlargement which is recorded by consecutive X ray examinations over years. The volume of a heart chamber indicates not only the stress to which it is subject and the state of its walls, but also its disposition to intracardiac thrombosis which notoriously adds gravity to the prognosis. In most cases of coronary thrombosis a mural thrombus is found post mortem in the left ventricle. In most cases of auricular fibrillation there are thrombi in the auricles. Treatment by quinidine does furnish one clear example of the possibility of the *prevention* of enlargement. Whenever a patient is seen shortly after the onset of auricular fibrillation, and it is the only sign found, it is our bounden duty to stop this arrhythmia by quinidine (possible, as a rule), not only to prevent the ensuing enlargement but also to avoid the consequent formation of intracardiac thrombi. Dr. Maurice Campbell (personal communication) from a recent analysis of patients treated with quinidine concludes that in deciding whether it is indicated or not, the duration of fibrillation and the size of the heart have almost equal importance. The prevention of enlargement is also brought into prominence by the wonderful effects of partial thyroidectomy in preventing or limiting an increase in heart size in goitre, though contrary to expectation it seldom reduces it.

The communication of the results of radiology to a cardiac patient is fraught with risk of misconstruc-

† On the pathology of the vessels of the pulmonary circulation, the several papers by Bronner in the Archives of Internal Medicine during 1935 may be consulted.

tion. Ignorance of a doctor's meaning can easily induce fear in the mind of a patient, and it is rather the place of a good physician to cast out fear. The best plan is to look upon X ray findings as a physical sign which does not or should not interest the patient except as a means of a fuller diagnosis. The worst of all is to mention enlargement to a patient and his friends when this is doubtful or absent. With a moderate grade of enlargement which conforms with the disease in question, a reassuring note may be sounded. When enlargement is absent the fact should be stressed as a good sign. If we cannot say something encouraging from the X ray examination, it is better to say nothing. The knowledge acquired from a routine X ray examination of the heart is as likely to influence the prognosis favourably as unfavourably. It is unwise to confront a patient with X ray findings as if they implied an added burden of sorts. Few outside the profession are able to visualise or to apprehend without fear what we might mean by saying that the heart is enlarged. In this respect I agree with a charming old lady who said: "Like most of your patients I suppose, I rather prefer to live in a fool's paradise." At least as Dr. Hutchison says<sup>52</sup> it is not every patient who is fit to be told the whole truth about his disease.

### Conclusion

Radiology can contribute to direct and exact knowledge in almost every variety of cardiac disease. Let us hope that our younger physicians will not be dilatory in working this field; for we in England are not in this respect yet in step with other countries. Though some will doubtless exaggerate its importance, it will steadily find its proper level among modern means of diagnosis. It is natural to regard with suspicion anything unfamiliar, and it is our duty to scrutinise any new method; but let not this defer our acquaintance with radiology of the heart—a novelty no longer. The modern physician will have his diagnostic powers extended and refined by adding radiology to his scheme of examination; he will supplement traditional methods by direct inspection of the internal organs.

In this office it is for me to express a considered opinion about enlargement of the heart and the means of its ascertainment. Cardiology is now an important and integral branch of general medicine, nothing more and nothing less. It will advance and develop beyond a post-mortem pathology which is static. By radiocardiology we shall reach a more vital anatomy and physiology, and—earlier in disease—a dynamic pathology of the living heart.

In the preparation of these two lectures I have to acknowledge the generous help I have received. I am grateful to Prof. H. M. Turnbull and Dr. W. W. Woods of the pathological department of the London Hospital; to Dr. William Evans, Dr. Clifford Hoyle, Dr. W. A. R. Thomson, Dr. J. H. Palmer, and others including my old friend, Dr. John Grimshaw of Birkenhead. Dr. Evan Bedford has been my constant collaborator.

## ACUTE TOXÆMIA OF BURNS

### EXTRACT OF SUPRARENAL CORTEX IN TREATMENT

By W. C. WILSON, M.B., F.R.C.S. Edin.\*

HON. SURGEON OF THE ROYAL HOSPITAL FOR SICK CHILDREN,  
EDINBURGH, AND LECTURER IN APPLIED PHYSIOLOGY  
IN THE UNIVERSITY OF EDINBURGH

G. D. ROWLEY, M.B. Edin.

AND

N. A. GRAY, M.B. Edin

(From the Royal Hospital for Sick Children, and the  
Department of Surgery, University of Edinburgh)

In this paper we record what seems to us a therapeutic measure of considerable promise for the treatment of one of the very dangerous early stages in the course of an extensive burn. The report is based on results in three cases only; we make no claim therefore to an established advance in treatment. Nevertheless our observations may be considered of value since circumstances permitted a very full investigation of the course in two of the patients and thus a comparison was possible with the course in a large number of cases similarly studied under strictly comparable conditions. Our object is to bring the method to the notice of others, in order that, while further clinical and experimental tests are proceeding, it may be generally available for trial and, as seems probable, for the saving of life.

#### Cause of Death in Burns

A brief reference is necessary to the results of an investigation into the cause of death in burns which has been carried out by one of us (W. C. W.) and others for several years past. The full details of the investigation will be published at an early date; some results have, however, been reported in previous papers<sup>1,2</sup> in which will be found a description of the clinical course and of the features of acute toxæmia.

Acute toxæmia, though only an occasional occurrence under present-day treatment of burns by

\* In receipt of a part-time grant from the Medical Research Council.

tannic acid, is still an important cause of death after extensive superficial burns and particularly in injuries affecting young children, in whom the clinical picture is characteristic and the illness often fulminating. The account given of the cases treated in this investigation will suffice for a description of the main symptoms and signs. It may be added that there is no characteristic change in the blood which can serve as a sure criterion of acute toxæmia and no constantly available method of assessment more accurate than observation of the signs of a failing circulation. This phase begins at any time between 6 and 50 hours after injury, and in severe cases death supervenes usually about 70 hours.

The only characteristic pathological change is severe necrosis and degeneration of the liver cells; the change is practically constant in cases which die between 50 and 100 hours, but may also be found in a proportion of those which survive for longer periods. As regards causation, it is practically certain that acute toxæmia is produced by the action of circulating toxins which have been formed by autolysis of injured tissue in the burned area. Increased concentration of the blood, early bacterial infection, and changes in blood chemistry are inconstant, and they are not essential causes of toxæmia.

The principles of treatment for most cases in the series studied were immediate coagulation of the burned area by a strong solution of tannic acid and, when necessary, maintenance of a normal blood-pressure level by intravenous infusion of gum saline. Our experience of treatment, however, includes not only various modifications of the tannic acid method but also other forms of local application; in general measures it embraces continuous as well as repeated intravenous infusions of normal saline, gum and dextrose saline, and also intravenous alkali. The point we wish to emphasise is that up to the present time, if acute toxæmia has developed in a severe or fulminating form, it has invariably proved fatal. Intravenous infusions may produce immediate but very evanescent benefit, and spontaneous improvement even for short periods of a few hours is rare.

In adults the manifestations of acute toxæmia are less prominent and less dramatic than in children. Typical features are vomiting, rise of temperature and pulse-rate, and mental changes such as anxiety, delirium, apathy, or stupor. Although death within 100 hours is the usual outcome of severe toxæmia,

some adults survive beyond the first week only to succumb under the added load of bacterial infection, or, in certain instances when infection is very slight, as a result of severe liver damage. It is therefore more difficult in adults to forecast the outcome or to judge the value of therapy.

### Clinical Report

Three cases are reported in which Eucortone, an extract of suprarenal cortex, was used as an adjuvant measure in the treatment of severe established acute toxæmia. The features specially studied were changes in the circulation, blood concentration, blood chemistry, and bacterial growth. The study was most complete in Cases 1 and 3; in Case 2 the opportunities for investigation were unavoidably restricted. It is proposed to describe only salient points of the course in each case.

#### CASE 1

Male, aged 3 2/12 years. Two hours before admission he was scalded by boiling water, the lesions involving about 20 per cent. of the total body surface.

*Treatment.*—Under nitrous oxide, oxygen, and ether anaesthesia the burned area was cleansed and 20 per cent. tannic acid and 1 per cent. gentian-violet were applied to the raw surface.

*Course.*—No shock was present on admission and no secondary shock developed. The first sign of toxæmia—vomiting of altered blood—appeared at 15 hours after injury. At 22 hours toxæmia became severe. The pulse-rate and rectal temperature rose rapidly; the systolic blood pressure remained unaltered but the pulse pressure decreased; there was marked restlessness combined with apathy. The skin became pallid, mottled, and cold; the lips, cheeks, and ears became ashen-grey, the eyes sunken, and the pupils dilated. In spite of reapplication of tannic acid on three occasions and intravenous infusion of gum saline at 43 hours the condition rapidly deteriorated. By 45 hours the heart-rate had reached 200 per minute and the signs of impending death were evident.

At 45 hours subcutaneous injections of eucortone were begun. After an initial injection of 0.5 c.cm., doses of 1 c.cm. were given 4-hourly. At about 30 mins. after the first injection of 1 c.cm. a distinct change was remarked. The skin had become warm, the areas of erythema around the tanned portions, previously obscured by pallor, had reappeared, the lips and ears were pink, and other signs of an active circulation in the capillaries of skin and mucous membranes were obvious. In addition the mental state of intense irritability, distress, and partial stupor had been replaced by one of quiet yet attentive restfulness. The injections were discontinued between 52 and 64 hours; the condition became again serious towards the end of the period, but improvement followed readministration of the extract which was carried on to 110 hours. By 82 hours all toxic signs and symptoms had disappeared, except that the temperature remained moderately elevated; the heart-rate had decreased to 120 per minute. There was no further recrudescence of toxæmia and the subsequent course was uneventful. The lesions were entirely healed by the thirty-fourth day.

Investigation revealed no noteworthy change in blood chemistry or blood concentration during toxæmia or subsequently during administration of eucortone. No organisms were found in cultures from the burned area up to 72 hours. A leucocyte count of 20,000 per c.mm. on admission decreased steadily to 6000 by 104 hours. The only change found in the blood after the injections of extract were begun was an increase in the sedimentation-rate (2 mm. to 27 mm.), which subsequently remained rapid.

*Comment.*—We have no doubt, judging from experience of similar cases, that acute toxæmia in this case would, but for the action of the extract, have proved fatal within a few hours. The beneficial effect was confirmed by withholding the extract for a period of 8 hours. The necessity for continued administration was established; here a total of

13.5 c.cm. was given, which was equivalent to 405 grammes of cortex. The course in this case suggested that formation or absorption of toxic principles from the burned area ceased at about 100 hours after injury, and showed that any damage suffered by important structures during the toxæmia had not been irreparable.

#### CASE 2

Female, aged 5. Thirty minutes before admission she sustained burns by fire, involving about 30 per cent. of the body surface.

*Treatment.*—The areas were cleansed under anaesthesia and 5 per cent. tannic acid was applied at intervals by spray.

*Course.*—The child remained restless in spite of sedatives. Toxæmia began at 13 hours with vomiting, which thereafter was frequent and repeated. At 15 hours the blood pressure was 60/40, the skin cold, pallid, and cyanosed, the pulse rapid and thready, the temperature raised, and delirium marked. By 24 hours the blood-pressure level had fallen so low that no accurate estimate could be made, and the condition was extremely grave.

Eucortone was injected every four hours in 0.5 c.cm. doses from 24 to 60 hours and in 1 c.cm. doses from 60 to 90 hours. No intravenous infusions were given throughout. At about one hour after the first injection the toxic manifestations began to recede and had entirely disappeared by 90 hours. Coincident with improvement in the peripheral circulation the blood pressure rose; the rise was steady and sustained. Some elevation of temperature, signs of bronchitis, and mild bacterial infection were the only abnormal features of the subsequent course.

*Comment.*—In this case the pronounced fall in blood pressure—an inconstant but particularly ominous event during acute toxæmia—provided a valuable additional index of the effects of therapy. Eucortone produced steady regression of well-established acute toxæmia. A total of 12 c.cm. was used, equivalent to 360 grammes of cortex.

#### CASE 3

Male, aged 49 years. One and a half hours before admission he sustained burns by fire which involved 25 per cent. of the body surface and in parts had penetrated deeply.

*Treatment* was as in Case 1. No intravenous infusion before the eleventh day.

*Course.*—There was no shock at 6 hours. He came under observation at 18 hours; a mild degree of secondary shock was present which passed off at 29 hours. The onset of acute toxæmia was at 32 hours; the rectal temperature and pulse-rate rose and vomiting of altered blood recurred at short intervals. At 41 hours he was cyanosed, irrational, vomiting every few minutes, and becoming exhausted by continuous hiccough. Alterations in blood chemistry were insignificant and the blood pressure remained at a normal level. There was, however, a conspicuous rise in corpuscular content of both capillary and venous blood.

Eucortone was injected in 2 c.cm. doses, at first 2-hourly, later hourly, from 41 to 87 hours and was followed by steady improvement. Vomiting stopped at 53 hours; hiccough, however, continued, though only at intervals and in milder form, till 93 hours. The pulse-rate and temperature fell; the skin developed a pink flush and the blood showed a gradual dilution. During this period a total amount was injected which was equivalent to 4020 grammes of cortex (a concentrated extract was used for part of the time).

On the eighth day signs of intoxication reappeared and again eucortone proved beneficial. On the eleventh day, when sloughs were beginning to separate in deeply burned portions, delirium, prostration, and incontinence of urine developed, which we were inclined, on the basis of previous experience, to ascribe to liver damage, although investigation yielded no evidence of this. Eucortone, injected hourly, certainly produced little obvious change at this stage and accordingly other methods were adopted.

Bacterial infection was certainly not in evidence before

the eighth day and was not gross at any subsequent time. The ultimate result was recovery.

*Comment.*—As already mentioned assessment of acute toxæmia is much more difficult in adults than in children. In this case, however, the degree of intoxication was such that we should not ordinarily have expected survival for more than 100 hours, and the conditions afforded a sufficiently severe test for the extract since no other measures, such as intravenous infusion, were employed to counteract a high blood concentration. The evidence of benefit from the use of the extract was clear. Events in the later stages of the course, however, suggested the question, to which an answer cannot meantime be given, whether toxic principles might injure the liver although coincidental effects on the circulatory and other mechanisms were controlled by extract therapy.

### Discussion

In the three cases quoted above acute toxæmia of burns had developed in a very severe form, and, in fact, a fatal issue within a short time could have been predicted in two of them with almost complete certainty. In our experience of these conditions recovery under any methods of treatment previously employed has not occurred. With every confidence we attribute the recovery in these cases to the administration of the extract of suprarenal cortex.

In 1920 Dale<sup>3</sup> found that previous removal of the suprarenal glands greatly enhanced the sensitivity of cats to the toxic action of histamine. Subsequently much evidence has accumulated from animal experiment of decreased resistance to many forms of intoxication after complete ablation of the suprarenals, and, since the production of active extracts of the cortex by Swingle and Piffner<sup>4</sup> and others, it has been possible to show that the loss of resistance is probably due to deficiency of cortex; the resistance of animals after suprarenalectomy to toxic agents can be raised significantly by administration of cortical extract.<sup>5</sup> In man cortical extract has been employed in a few instances in the treatment of bacterial infections and toxicosis; so far as we are aware no reports are available of its use in burns.†

Regarding the mode of action of suprarenal cortex extract in combating acute toxæmia of burns we have little positive information. Our observations indicate that it results in an increased efficiency of the circulatory mechanism. The only alterations found in the blood of burned individuals during extract therapy were in the sedimentation-rate, and (once) in corpuscular content. There is no satisfactory evidence that acute toxæmia of burns produces a functional insufficiency of the suprarenal glands; changes in blood chemistry during the toxic phase of burns, though in certain instances they bear some resemblance to changes after suprarenalectomy, are irregular and frequently insignificant. Moreover, pathological studies have revealed little evidence of damage to the suprarenals; indeed we were so influenced by the absence of this evidence that we postponed the trial of the cortical extract in acute toxæmia for several years. Further investigation on the action of the extract is required, and mere speculation without basis of fact would be fruitless.

On the grounds of our limited experience of extract therapy we might venture to make tentative suggestions for treatment. Suprarenal cortical extract should be considered as an adjuvant measure, and

not as a substitute for proved and recognised preventive treatment, in acute toxæmia of burns and also possibly, as future trial may show, in the stage of circulatory collapse which we call "secondary shock." We regard as essential, however, the employment of local and general measures<sup>1, 6</sup> which have been designed especially to combat secondary shock and to minimise acute toxæmia and sepsis. In the present state of our knowledge it would be unwise to assume that exhibition of the extract will annul completely all effects of toxæmia, and therefore some precaution against liver damage is advisable. We have evidence that continuous intravenous infusion of dextrose saline from an early stage of extensive and severe burns may mitigate the injury to the liver cells. The quantities of extract required for maintenance of circulatory efficiency are evidently considerable. Of the concentrated extract now available (Allen and Hanburys Ltd.) 1 c.cm. every 2 hours from the onset of acute toxæmia will suffice for a child, while for an adult 2 c.cm. or more every hour are necessary. Injections should be continued till 100 hours after injury and should be renewed if toxic manifestations reappear. (1 c.cm. of this extract is equivalent to 75 grammes of cortex.)

Case 2 was under the charge of Mr. J. C. Anderson, assistant surgeon at the Royal Hospital, Sheffield, and Case 3 under the charge of Mr. A. Pirie Watson, surgeon at the Leith Hospital. We are greatly indebted to them for permission to publish the reports. It is a particular pleasure to record our appreciation of the nursing skill in the care of burns of Nurse A. K. Smith, Royal Hospital for Sick Children, Edinburgh.

## THE EFFECT OF OÖPHORECTOMY AND SPLENECTOMY ON CANCER OF THE BREAST AND UTERUS

BY PETER PATERSON, M.B., F.R.F.P.S. Glasg.

EMERITUS PROFESSOR, ST. MUNGO CHAIR OF SURGERY, UNIVERSITY OF GLASGOW; CONSULTING SURGEON, GLASGOW ROYAL INFIRMARY

It is fairly generally recognised that in cancer two factors have to be considered to explain the unlimited multiplication of the cells with secondary spread to other parts—namely, an abnormal stimulation of the cells of the parts primarily involved, and a medium in which these can grow. The latter seems to me by far the more important, and I believe that there exists a condition conducive to the onset of the disease and persisting throughout its course. If such a state were absent, either the tumour would never begin or it would remain local, because cells transferred to other parts of the body would perish in their new surroundings.

Local irritation, of a more or less trivial character, may be the exciting cause in some cases, but there are many others in which no local irritant can be found; and, on the other hand, there are individuals who have been exposed for years to a definite local irritation and yet have remained free from the disease. Innumerable investigations have been made to find

† In a personal communication to one of us Mr. Harold Dodd states that he has used the extract in burns with benefit.

if, and what, changes take place in the tissues and metabolism of the infected person, and though many differences between the healthy and the diseased have been described, none has been recognised as being the definite underlying cause; in fact many of these may only be the result of the presence of the tumour. I am not in a position to offer an opinion as to what that change is, but I believe it does exist and further, that it may, in exceptional cases, be only temporary, since a considerable number of cases are on record in which malignant tumours have disappeared spontaneously. To these the two following may be added.

#### SPONTANEOUS RECOVERIES FROM SARCOMA AND CANCER

CASE 1.—Twenty-five years ago I removed a chronically inflamed appendix from a young woman. A normal convalescence followed, but a year later she again consulted me complaining of vague pains in the right iliac fossa. Palpation showed the presence of a slightly tender mass about the size of the fist in the region of the caecum. I again operated and found a tumour involving the whole caecum which was fixed to the iliac fossa and irremovable. A small piece was excised for microscopical examination and the wound closed. The tissue removed was submitted to the late Prof. J. H. Teacher, who reported that the tumour was a spindle-celled sarcoma. As a result of damaging the caecal wall an abscess formed and discharging through the wound, remained open for several weeks. The only pathogenic organism found in the pus was the *Bacillus coli*. Growth was now rapid and in a few months the tumour filled the greater part of the right side of the abdomen, reaching from the liver to the pelvis; it extended almost to the middle line in front, and halfway down the thigh. At this stage the patient's condition was very poor and there was much emaciation. Then, for no obvious reason, the mass began to shrink, and it continued to do so till it disappeared. To-day the patient is alive and well.

CASE 2.—The second patient is a woman on whom, 18 years ago, I performed a laparotomy for a carcinoma of the stomach. As there were secondary nodules in the liver, nothing further was done except to close the abdominal wound, and yet this patient is to-day apparently quite well. The diagnosis in this case was also confirmed by microscopical examination of a gland removed at the operation.

In these cases either the tumour cells stopped growing because of some change in the cells themselves; or the resistance of the tissues had been so raised, either by addition or subtraction, they were able to overcome the abnormal growth.

#### OÖPHORECTOMY AND SPLENECTOMY

Recently attention has been directed to the endocrine glands as possibly having some influence on the onset and course of these tumours. Before the important place that endocrines take in metabolism was appreciated, the late Sir George Beatson held the opinion that the ovaries took some part in the aetiology and course of this class of tumour, and recent investigations seem to support his contention. Acting in that belief, he performed a double oöphorectomy on two patients suffering from cancer, but without arresting the course of the disease.

The high degree of immunity presented by the spleen to cancer, either primary or secondary, has not escaped the notice of those who have been trying to find something that would have a beneficial influence on the course of the disease once it had become established and many attempts, in which I have shared, have been made to control its progress by injections of various forms of splenic extract. The extract I used was prepared for me by Dr. D. P. Cuthbertson, late of the biochemical department of

the Glasgow Royal Infirmary, by a method similar to that employed in the preparation of insulin. The conclusion I came to as a result of these injections was that growth was stimulated, and the larger the dose, the more rapidly did it advance. If these observations were correct, the question now arose, would removal of the spleen have any influence on the disease? I resolved to try, if a suitable case presented itself.

CASE 3.—In May, 1931, a woman, aged 41, came under my care in the Royal Infirmary who, two years previously, had had her uterus and both ovaries removed for an adenocarcinoma of the uterus. When I saw her she had a tumour in the pelvis which had invaded the rectum on the one side and the bladder on the other. There was a discharge of blood, pus, and mucus from the rectum with considerable pain during defaecation. Micturition was frequent, about once every two hours, and was painful. The urine contained pus and blood, the latter quite visible to the eye. Rectal palpation revealed a fixed ulcerating mass in the anterior wall of the rectum. Cystoscopic examination showed a large irregular ulcerating tumour towards the base of the bladder with phosphatic deposits scattered over the surface of the growth. Pain was so severe she required narcotics to get sleep and secondary anaemia was well marked.

A left inguinal colostomy was performed and at the same time the spleen was removed. Intra-abdominal palpation revealed an extensive glandular infection. Six weeks later she was given daily injections of fairly large doses (4 c.cm.) of splenic extract. These injections were continued for six weeks. At the end of that time the condition was worse. The rectal ulcer was larger; the blood in the urine was sufficient to make it blood-red and her appetite had almost disappeared. The dose of extract was then reduced to 1 c.cm. daily and continued for two months. At the end of that time she began to improve; rectal pain was less and blood in the urine could only be found by reagents. She could sleep without narcotics; appetite was better and she began to gain weight. Improvement was slow but steady till at the end of a year no trace of the disease could be found in the rectum, pelvis, or bladder, a cystoscopic examination of which showed a smooth whitish patch where the tumour had been situated. I still see her occasionally, and at present, nearly four years after the disappearance of the disease, there is no evidence of a recurrence; she feels quite well and has gained 3 st. in weight.

Subsequently, splenectomy was performed in several patients who were suffering from inoperable cancer. A few of these had no other treatment; others were exposed to deep X ray therapy, whilst others had injections of splenic extract in various doses; but in all of them the disease ran its course, so that evidently the result obtained in the first case was not due to splenectomy alone. In nearly every one of these cases the spleen was more or less adherent to some of the surrounding structures, probably as the result of perisplenitis, though nothing abnormal could be found in the spleen itself on microscopical examination.

It was next decided to remove both ovaries and spleen in a patient who had an inoperable carcinoma, if such could be found who would consent to the operation.

CASE 4.—In July, 1935, a woman, aged 46, presented herself at the Infirmary with a cancer of the right breast which she had known to be present for at least a year. She was emaciated and her appetite was only fair; she had very little pain. The breast, which was not large, was infiltrated with a hard nodular mass and was firmly fixed to the chest wall. A chain of enlarged glands, each about the size of a cherry, extended along the anterior axillary wall into the apex of the axilla, and there were several hard red nodules in the skin over the breast and also in the skin of the chest wall in the immediate neighbourhood, showing a widespread lymphatic involvement.

After explaining to her what the double operation meant, and having obtained her consent, I removed the spleen and both ovaries on July 24th, and also one of the glands for examination. The pathologist reported that the gland was infiltrated with adenocarcinoma. Apart from the removal of spleen and ovaries no other treatment has been given. The disease appeared to remain stationary for about four months and then commenced to improve. When I last saw her at the middle of May—i.e., about ten months after operation—the enlarged axillary glands were no longer palpable, the cutaneous nodules had all disappeared, and the breast was a shrivelled fibrous mass. There was in fact no sign of active disease, and the patient had gained a stone in weight.

I can offer no explanation as to what metabolic changes take place as a result of double oöphorectomy with splenectomy; that belongs to the province of the biochemist and physiologist. But apparently the removal of either ovaries or spleen does not influence the course of the cancer, nor does removal of the spleen alone make patients immune from it. McNee, for example, mentions two cases in which cancer of the buccal cavity has appeared three years after splenectomy.<sup>1</sup>

It is known that after removal of the spleen its functions, so far as they are related to the cellular elements of the blood, are taken up by other structures, especially the bone-marrow, and it is thought to take some part in preventing septic infection; but beyond that we are ignorant. Even its structure is a subject in which there are differences of opinion. Like the other ductless glands, it may secrete a hormone, but if such does exist, it is probably of minor importance in the general metabolism, since its removal does not prevent good health; but the same is true of the ovary, which undoubtedly has an internal secretion. Perhaps there is an inter-relationship between the two glands, or they may act on other endocrines through that distributing centre, the pituitary.

The cases here submitted are far too few to serve as basis for general conclusions; and from circumstances beyond my control I am no longer in a position to continue the investigation. But few though they are, they may possibly serve as a guide to other workers in this field.

## COUNTER-IRRITATION BY ULTRA-VIOLET LIGHT

By ALBERT EIDINOW, M.B. Lond.

HONORARY CONSULTING PHYSICIAN IN CHARGE OF THE LIGHT  
DEPARTMENT AT THE RADIUM INSTITUTE AND AT THE  
ST. JOHN CLINIC AND INSTITUTE OF PHYSICAL  
MEDICINE, LONDON

COUNTER-IRRITATION is an ancient method of therapy. Discovery in chemistry or physics has evolved many new methods; innumerable chemical reagents are now recognised for their action as rubefacients or vesicants. Physical agents producing heat, electricity, or friction are also used.

The ultra-violet rays that cause erythema of the skin can be successfully employed for counter-irritation. Wave-lengths shorter than 3000 Angstrom units applied to the normal white skin cause erythema after a latent period of 4-6 hours. The dosage and technique of irradiation controls the degree of skin reaction that results. This can be varied so as to cause a mild erythema or a definite or severe blistering of the skin. Ultra-violet irradiation is therefore

excellent for counter-irritation, as the rays can be directly applied to any area and the degree of reaction can be accurately defined and controlled. With the chemical and other counter-irritants, this is not always possible in practice; the strength of drugs such as mustard is difficult to regulate and often their application has to be repeated until the desired skin reaction is obtained.

### THE REACTION

The classical pharmacological studies of the action of irritant agents on the skin describe general, local, and special reflex effects on the body. Naturally the severity of the reaction varies with the strength of the irritant applied.

The general effect of counter-irritants follows immediately; stimulation of the sensory nerves causes mild contraction of the blood-vessels in the splanchnic area, with rise of blood pressure, accentuation of heart-beat and of respiration. The sudden application of a severe irritant may cause sufficient damage to produce the signs and symptoms of surgical shock with fatal collapse.

The local effect may be a mild redness of the skin due to dilatation of blood-vessels at the site of application; a sensation of warmth and anaesthesia is felt. The exudation of plasma and lymph and transudation of fluid through the skin tissues causes signs of oedema, blistering, or even pustulation and necrosis, with symptoms of local discomfort, pain, and irritation.

The special reflex reaction is still a problem of much interest and recognised importance. Little progress has been made since the days of Head and Mackenzie. Reflex stimulation of viscera by trophic nerves, far remote from the site of application of irritant but connected by nervous channels, may explain many of those intricate cases that have successful and immediate relief from pain. At times counter-irritation to an area of skin clears up mysteries of what lies in the remote depths of the body. This is constantly observed, but the therapeutic action is still unexplained.

Skin erythema appears about 4 hours after ultra-violet irradiation; a maximum reaction results about 48 hours later and this erythema may persist for 3 or even up to 12 days, with intensive dosage. With still increased intensity of radiation, oedema and blistering are produced; this effect may be obtained by increasing the strength of the ultra-violet rays emitted by the source of light, by diminishing the distance between the skin and the source of rays, or by increasing the length of exposure. The dose of rays can be accurately determined and expressed in terms of skin erythema doses; usually from 6-10 skin erythema doses are applied for counter-irritation therapy. Following the erythema, oedema, and blistering of the skin, there is drying and desquamation. Pigmentation finally results. The dilatation of the skin capillaries in an area of irradiated skin persists for many months; this phenomenon can be clearly demonstrated, for if 1 c.cm. of histamine phosphate solution, containing 0.003 g. of histamine base is injected subcutaneously an intense erythematous blush appears 10-15 mins. later in the irradiated skin; the surrounding area does not show any visible change.

The erythema and blistering reaction of the irradiated skin is painful and uncomfortable. This is a very serious complication, for the symptoms are often so severe and unpleasant that the patient becomes greatly distressed and has to go to bed.

<sup>1</sup> McNee, J. W.: THE LANCET, 1931, i., 1011.

Special dressings for the blistered skin area and sedative medicines are necessary. Fortunately this painful reaction can be checked and at times successfully avoided. Directly after irradiation, adhesive Elastoplast strapping is applied to the irradiated skin and the surrounding area. This greatly diminishes the painful symptoms, but in no way alters the reaction. The strapping is kept on and left undisturbed for 14 days; it is then removed and the irradiated skin is exposed, revealing a reddish-brown moist area. Pigmentation varying in colour from a pale to a dark brown will finally develop. The relief of the painful symptoms obtained by the application of strapping is indeed most remarkable, for by this means it is possible to apply 10-12 times the normal skin erythema dose of ultra-violet rays to an area of normal white skin without unduly disturbing the patient. Intensive erythema, œdema, and exudation must develop in the protected skin area. The strapping remains comfortably in position and when it is removed 14 days later the desquamated skin is shed simultaneously. It is necessary to explain emphatically to the patient that the strapping must not be disturbed for 14 days. If this skin area is still painful, infra-red rays can be applied, two or three times a week, to this region, the strapping being left undisturbed.

#### METHOD OF APPLICATION

The area of skin selected for ultra-violet irradiation is mapped out carefully with a dermatograph pencil. The time and distance factors of dosage are also indicated by writing on the skin, so that accurate information will be directly available at the time of treatment. The surrounding skin area is protected from the rays of the lamp by a covering of pieces of crêpe paper attached by strips of adhesive plaster or strapping. Towels or other simple means of protection may be employed. The irradiated area is accurately exposed according to the prescribed formula. Usually a skin area measuring roughly 12 by 10 in. is exposed. A quartz air-cooled mercury-vapour lamp operated by a current of 2.5 amperes and 140 volts between the electrodes is switched on. At a distance of 12 in. between the quartz burner and the skin area, an exposure for 20 mins., equivalent to ten normal erythema skin doses, is applied. This irradiated skin area and the surrounding skin margin extending for 1-2 in. is immediately covered by overlapping strips of adhesive plaster 2-2½ in. in width. The dermatograph pencil marks are removed. The patient is instructed to leave this plaster undisturbed for 14 days. During this period it may be necessary to report for further consultation or for further treatment such as the application of infra-red rays 2-3 times a week. If infra-red and luminous irradiation are necessary the rays are applied to the selected area but the strapping is not disturbed.

Some patients complain of some discomfort during the second or third day, others complain of itching of the skin on the seventh to ninth day. Usually these symptoms are of no serious consequence and do not necessitate any special interference or local treatment. Two weeks following treatment the strips of strapping are removed, the skin area is cleansed with methylated ether or oil of eucalyptus. A moist red or a pigmented yellow-red area of skin is seen. Skin desquamation and a full exudative reaction has occurred beneath the plaster quite unknown to the patient. Further infra-red irradiation may be applied to this area, but local ultra-violet irradiation is contra-indicated as the area will

be highly resistant and immune to a further erythema reaction for some weeks. In hospital practice patients receiving local intensive ultra-violet irradiation are usually made to report seven days after treatment. If symptoms are present or the site of pain has now altered in its position, a further treatment to a new skin area may be prescribed.

#### INDICATIONS

The types of cases selected for treatment by this technique of intensive ultra-violet irradiation were those in which symptoms of acute pain were present (brachial and sciatic neuritis, lumbago, fibrositis, &c.); those in whom there was swelling of joints due to effusion of fluid; those with symptoms of asthma, with dyspnoea, and a definite history of frequent attacks of troublesome respiration.

*Acute pain.*—Painful symptoms due to cervical fibrositis, brachial neuritis, lumbar fibrositis, lumbago and sciatic neuritis were treated. Early cases with symptoms of sudden onset of acute pain and signs of rigidity and limited movement rarely visit the out-patient departments of hospitals and clinics. Usually they first consult local practitioners and are put to rest in bed and given medicinal treatment. Symptoms may completely subside within 5-7 days. It is difficult to assess the value of treatment in this one group, for though signs and symptoms clear up rapidly after local ultra-violet counter-irritation treatment and the success is attributed to the treatment many of these acute attacks of muscle and nerve inflammations may possibly clear up independent of treatment.

The cases in which the symptoms persist are the type commonly seen in hospitals. Those patients, who complain of pain in neck radiating to the shoulder and arm, were treated by the application of the rays of the air-cooled quartz mercury-vapour lamp, to an area of skin over the cervical area passing to the shoulder and arm. At a distance of 12 in. from the source of light the skin was irradiated for 20 mins. This was immediately covered with strips of elastoplast strapping. Infra-red rays were also applied three times a week to this area. Two weeks later the elastoplast strapping was removed and the area of red-brown coloured moist skin was exposed. As a rule pain was quickly relieved and the movements of shoulder were free or greatly improved. It was sometimes necessary that the infra-red irradiation should be continued three times a week for a further fortnight. At times patients stated that the symptoms in the shoulder had disappeared, but pain in arm or forearm was present. In these cases, intensive irradiation was applied to another skin area corresponding to the site of pain.

Lumbar pain was similarly treated but the painful and tender skin area of the back indicated by the patient was irradiated. Usually the size of the area was 10 by 12 in. In the successful cases relief of symptoms was reported after the first treatment.

Sciatic neuritis was treated by irradiation of the skin over the buttock and the skin of the back of the thigh. The results were satisfactory in about 60-70 per cent. of cases. In general, early cases in which symptoms were of a shorter duration responded most favourably. Local infra-red irradiation was always prescribed. At times the position of pain changed and was referred to the calf and outer side of the foot. Ultra-violet irradiation was never repeated over the same area of skin, but a new skin area over the back of the thigh or the calf was selected for further treatment after an interval of 14 days. Severe chronic sciatic neuritis of long duration with signs of muscle wasting and partial nerve paralysis needed longer treatment, with continued infra-red irradiation twice a week for 6-8 weeks. The counter-irritation always helped to relieve the acute painful symptoms.

*Swollen joints.*—Intensive local ultra-violet irradiation of the skin over swollen joints will at times reduce the degree of swelling and allow freer movement. Unhappily chronic and subacute infective arthritis does not respond as well or as consistently as traumatic arthritis. Naturally the most favourable cases are those following recent injury in which there is subacute synovitis with fluid

effusion. The conditions of monarticular arthritis deserve perseverance with this therapy. Ultra-violet irradiation hastens the absorption of fluid and resolution of inflammation.

*Asthma.*—It is very surprising to be able to record favourable results in isolated cases of chronic asthma. The patients selected at the clinic for this treatment were those who definitely expressed the severity of their symptoms. Long-standing asthma with signs of bronchitis and emphysema, giving a history of symptoms of urgent dyspnoea, was at times greatly relieved. All cases were treated by the same method. An intensive local application of ultra-violet rays was applied to an area (10 by 12 in.) of the skin of the back of the chest. The patients who responded favourably within the following 7-14 days and who stated that their symptoms were relieved were given a second treatment to the skin of the front of the chest. During the first 2-3 days following treatment coughing was more frequent and expectoration freer and more copious; dyspnoea was diminished and respiration improved. Clinically these patients have signs of chronic bronchitis and emphysema and therefore the value of treatment can only be assessed by the remarks of the patient, but these were favourable.

#### CONCLUSIONS

No argument or theory explaining these results will be expressed; a definite maximum counter-irritation reaction of the skin has been established by means of ultra-violet irradiation. The painful symptoms and discomfort usually following such measures have been greatly lessened by the immediate application of elastoplast strapping over and beyond the irradiated skin area. Total or partial relief of symptoms often follows treatment. The value of counter-irritation has already been well established, but the use of ultra-violet rays for this purpose affords a new and practical method of application, for any desired area of skin can be selected and the degree of skin reaction can be completely controlled at will.

### CHEMICAL CHANGES IN THE BLOOD IN ADDISON'S DISEASE AND THEIR ALTERATION IN RESPONSE TO TREATMENT

BY ERIC NEWMARCH ALLOTT, B.Sc., B.M. Oxon.,  
F.R.C.P. Lond.

PATHOLOGIST, LONDON COUNTY COUNCIL GROUP LABORATORY,  
LEWISHAM HOSPITAL, S.E.

RECENT developments in the treatment of Addison's disease date from 1926, when Baumann and Kurland<sup>1</sup> studied the effect of adrenalectomy on the electrolyte pattern of the blood in cats and rabbits, and Marine and Baumann<sup>2</sup> showed that the life of the adrenalectomised animals could be prolonged by the administration of sodium chloride. The first application of these results to human cases of Addison's disease was published by Loeb<sup>3</sup> in 1932.

Meanwhile, in 1930, Swingle and Piffner<sup>4</sup> had isolated a hormone from suprarenal cortex which was active in relieving symptoms of suprarenal insufficiency: numerous publications have confirmed the value of this in cases of experimental adrenal insufficiency, and in Addison's disease, though the exact position as regards its proper employment is at present not clear. Harrop, Weinstein, Soffer, and Trescher<sup>5</sup> state that cortical extract has no definite effect on hypotension or pigmentation and are not convinced that it has any effect on nutrition and weight. They stress that its principal

importance is in the treatment of relapse. Snell<sup>6</sup> also states that in the chronic phase of the disease no striking clinical effect is to be expected from the administration of cortical extract, and Rogoff<sup>7</sup> found that Eschatin was of no value in restoring suprarenalectomised cats, and suggests that improvements caused by its administration are due to the water and salt given along with it. Kendall<sup>8</sup> has separated two active fractions from an adrenal cortex extract, one of which produced results only when salt was given with it.

It seems therefore desirable at present that every opportunity should be taken to study cases of Addison's disease as fully as possible, and the following paper gives the results of the chemical findings in eight cases of Addison's disease. The patients were scattered in various hospitals, and it has not been possible to carry out the investigations in every case as fully and systematically as one would wish.

#### BLOOD CHEMICAL CHANGES IN SUPRARENAL INSUFFICIENCY

The characteristic blood changes in experimental suprarenal insufficiency consist of a fall in the sodium and chlorine content of the serum, a rise in the potassium and magnesium, a retention of nitrogen (high blood-urea and non-protein nitrogen), and increased concentration of the blood (high oxygen capacity and hæmatocrit values and high serum protein). These findings have been noted in rabbits and cats<sup>1</sup> and dogs (Loeb, Atchley, Benedict, and Leland<sup>9</sup>) but Levy Simpson, Dennison, and Korenchevsky<sup>10</sup> found serum chlorine normal in adrenalectomised rats.

In untreated cases of Addison's disease changes very similar to the above have been noted by Loeb, Harrop, and others, though Snell<sup>6</sup> states that during the chronic or stationary period of the disease the composition of the blood and electrolyte pattern

TABLE I

In this table and Table II. the figures without parentheses indicate mg. per 100 c.cm. serum, except for HCO<sub>3</sub> ( vols. per cent.) and total protein (g. per 100 c.cm.); figures in parentheses indicate milli-equivalents per litre of serum. (Values for protein calculated from sum of albumin and globulin, not shown in tables.)

FINDINGS ON ADMISSION

FINDINGS IN CRISIS				
3	244 (106)	31.2 (8.0)	—	91
4	219 (95.5)	28.0 (7.2)	235 (66.2)	44†

\* Non-protein nitrogen.

† This value was so surprising that it was checked twice, with the same result.

are within normal limits. The rise in blood-urea seems the least constant of these changes. Levy Simpson<sup>11</sup> found blood-urea normal in 2 cases out of 6 and Rowntree<sup>12</sup> found it above 50 mg. per 100 c.cm. in only 4 out of 12 cases. In crisis the blood-urea is more constantly high, though even here there are exceptions (see Case 4). It has been possible to restore the blood composition of human sufferers

approximately to normal figures in many cases by treatment with sodium salts with or without cortical extract.

Of the cases described in this paper all showed to a greater or less extent these changes on first observation, as shown in Table I. Two of the patients went into crisis (Cases 3 and 4) while under observation, and the abnormality already present was greatly exaggerated under these circumstances; in crisis there is frequently a marked rise in the non-protein nitrogen, but in Case 4, which was fatal, the blood-urea actually fell.† Of the eight cases described in this paper, four (Nos. 1, 3, 5, and 6) were improved sufficiently to leave hospital; one (No. 4) died in crisis; one (No. 2) died on cessation of treatment with cortical extract; and two (Nos. 7 and 8) were not diagnosed with certainty before death, though in both cases the blood pressure and chemical findings made the diagnosis of adrenal insufficiency a very probable one. Of the four discharged one (No. 1) is untraced, two (Nos. 3 and 5) died a month after discharge, and one (No. 6) is still alive.

CASE REPORTS

**CASE 1.**—A man aged 36, a painter, was admitted to Charing Cross Hospital on Oct. 3rd, 1934, complaining of loss of appetite and languidness with vague onset in November, 1933, and becoming worse till June, 1934. There was nausea, but no vomiting; anorexia; never any diarrhoea. Pigmentation noticed in April, 1934, and got worse till July when he became "as black as a penny," then gradually better, more rapidly under treatment. Weight: 1933, 8 st. 7 lb.; June, 1934, 7 st. 2 lb.; October, 1934, 6 st. 7 lb.

*Examination.*—Generally dark; small areas of pigmentation on face, trunk, flexures and pressure points, and inside of mouth. Hand-grip weak; blood pressure, 86/65; otherwise normal. Radiography: no evidence of tuberculosis of lungs; no suprarenal shadows.

*Progress.*—While in hospital the patient continued to improve, irrespective of what treatment was given, and he was discharged feeling nearly fit for work on Nov. 20th, with instructions to continue with 10 grammes of salt daily. Subsequent efforts to trace him have failed.§

*Blood pressure.*—Varied between 70/50 and 95/60, but there was no sign of any alteration in response to cortical extract or salt.

*Chemical findings* (Table II.).—The serum sodium and chlorine remained low throughout, and showed no significant alteration, in spite of clinical improvement.

**CASE 2.**—A woman aged 51, in domestic work, was admitted to Hackney Hospital on Jan. 4th, 1935, complaining of headache, nausea, sickness, and pigmentation for a year; weakness for three weeks. She had been subject to attacks of headache and sickness all her life: these were worse during the last year. Pigmentation was noticed one year ago. No loss of weight noticed. Tired during last three weeks: extremely fatigued for last fortnight.

*Examination.*—Drowsy, retching, sweating. Uniform pigmentation of skin and mucosa of mouth; weak. Blood pressure 88/65. Arthritis of both knees. No other physical signs of disease. No radiographic evidence of tuberculosis; no definite suprarenal shadows.

*Progress.*—Treatment with Eucortone started on Jan. 21st: the patient was exceedingly weak before, but rapidly felt stronger and brighter under treatment. There was pyrexia up to 103° the day after the treatment began, but after this the temperature remained normal, with occasional rises to 99°, till the beginning of March, when diarrhoea commenced with pyrexia; these symptoms persisted till shortly before death, but no pathogenic organisms could be found as a cause. Blood pressure varied over a wide range, but there seemed a definite

rise of systolic pressure under cortical extract (Fig. 1). Treatment with salt was attempted from Feb. 21st, but the patient failed to keep all the salt down when given by mouth, and could not retain rectal saline; so the amount of salt was never really the full 15 g. per day. The improvement in the clinical condition under cortical extract was definite, but it was not considered justifiable on the grounds of expense to go on with 30 c.cm. of cortical extract daily, and cortical extract was stopped on March 28th. The patient slowly sank and died on April 12th. Permission could not be obtained for a post-mortem examination.

*Chemical findings* (Table II. and Fig. 1).—Under the enormous doses of cortical extract used there was very

FIG. 1 (Case 2).—To show blood dilution and fall in potassium and urea with little change in sodium and chlorine in spite of massive doses of cortical extract. Note the rise in potassium, urea, and protein when cortical extract is omitted.

little tendency for the sodium and chlorine to return to normal. There was, however, evidence of retention of fluid in the blood shown by fall in plasma proteins from 6.55 to 4.96 per cent. under treatment: on cessation of administration of cortical extract, the potassium and urea rose again to pathological values, and plasma proteins rose to 5.9 per cent., indicating a loss of fluid from the blood.

**CASE 3.**—A woman aged 43, a housewife, was admitted to Charing Cross Hospital on March 30th, 1935, complaining of being run down since the shock of an accident to her son 18 months previously. Five weeks before admission she had diarrhoea and since then she had suffered from "wasting and anæmia."

*Examination.*—Poor condition. General pigmentation, most marked over pressure points, and pigmentation of mucous membrane of mouth. Blood pressure: 100/? as out-patient but 70/50 on admission to ward.

*Progress.*—From admission to April 30th she was treated with 5 c.cm. eschatin twice weekly, with some improvement, but on April 30th she rapidly sank and became drowsy and sick and lost her appetite, and the

† In Loeb, Atchley, Gutman, and Jillson's case<sup>11</sup> the non-protein nitrogen fell when the patient went into crisis.

§ The Registrar-General has kindly informed me that no record of this patient's death has been registered up to June 30th, 1935.

blood pressure fell to 55/?. She was rescued from crisis by intravenous administration of 6.5 c.cm. eschatin (all that was available at the time) and rectal salines, and then treated with cortical extract (10 c.cm. a day—subsequently reduced to 5 c.cm.) and salt (15 g. in capsules) daily. By May 22nd she had practically normal blood electrolytes and was feeling very well and putting on weight. Cortical extract was then stopped, the salt being continued. She continued to improve clinically, feeling stronger all the time but her blood gradually became abnormal, and on June 25th cortical extract (5 c.cm. alternate days) was recommenced. She was discharged from hospital, much improved, on July 9th, taking 15 g. salt daily and 5 c.cm. eschatin twice weekly, but died at home in crisis on the 30th. Blood pressure, apart from crisis, varied between 80/50 and 90/60 most of the time in hospital.

*Chemical findings* (Table II.).—By the use of salt and cortical extract a nearly normal blood picture was attained, but on cessation of cortical extract the potassium and urea gradually began to rise, followed by a fall in the sodium and chlorine. The addition of small doses of cortical extract gradually altered the blood composition towards normal, though normality had not quite been reached again before discharge.

CASE 4.—A man aged 35, a labourer, was admitted to St. Andrew's Hospital, Bow, on May 24th, 1935, complaining of lethargy, anorexia, and dyspnoea. He had never been really well since a partial thyroidectomy in 1919 for Graves's disease. For four years he had noticed increased pigmentation of skin, more marked in summer, his friends saying "he looked like a black man." For seven months he had had increasing lethargy, anorexia, and dyspnoea, much more during the last two months.

*Examination.*—General condition poor. Marked exophthalmos. Universal pigmentation of skin and buccal mucosa. Thyroid gland (L) large: scar of thyroidectomy on right side.

*Blood pressure* 105/80. No radiographic evidence of tuberculosis. No suprarenal shadows. Basal metabolic rate: minus 37 per cent.

*Progress.*—An oral suprarenal preparation was tried, but without improvement; on June 13th he went into crisis and died suddenly on the 14th.

*Post-mortem.*—No definite adrenals could be found: on right side a small cyst was found in the position of the suprarenal, but sections did not show any adrenal tissue.

*Chemical findings* (Table II.).—The blood on June 4th showed in a very marked degree the typical changes of the condition; blood taken in crisis on June 13th showed more exaggerated changes: the rise of hæmoglobin from 82 to 88 per cent. is evidence of blood concentration. In this case the blood-urea did not rise during crisis (cf. footnote (†) on page 1407).

CASE 5.—A coffee-stall keeper, aged 48, admitted to Charing Cross Hospital on May 18th, 1935, complaining of loss of energy and appetite, pigmentation, and loss of weight. Loss of energy noticed during last year, pigmentation had come on over same period. He had lost 2 st. in last fifteen months. Vomiting occurred once, three weeks before admission. Slight hæmoptysis once, some months before admission.

*Examination.*—Not particularly wasted; dark colour but no special distribution of pigment noticed. No definite pigmentation of buccal mucosa. Blood pressure on admission 106/80, but subsequently usually between 98/70 and 80/50. No other physical signs, except impaired percussion note at right apex. Radiography: no evidence of tuberculosis in chest; no suprarenal shadows. No tubercle bacilli found in sputum.

*Progress.*—After a control period of a week the patient was treated with eschatin, 5 c.cm. per day for one week; no significant change took place in the clinical condition during this period. After a further week, salt (15 g. a day) was given and on this treatment the patient began to feel stronger. He continued to gain strength, and was discharged feeling well on July 25th. He was instructed to continue taking 15 g. of salt a day. His weight on admission, 11 st. 10½ lb., fell to 11 st. 5½ lb. on June 9th, and then gradually increased again to 11 st. 10½ lb just before his discharge. He died at home on August 19th

from acute osteomyelitis of the jaw, though otherwise he had kept well.

*Chemical findings* (Table II.).—Here again the potassium and urea came down to normal before there was any change at all in the sodium. There was evidence of increase of blood volume, the hæmoglobin falling from 102 to 80 per cent.

CASE 6.—A woman aged 47, a housewife, was admitted to St. Alfege's Hospital on Jan. 8th, 1936, complaining of loss of appetite and pigmentation: for last two months she had been very easily tired and was unable to do housework. She had got darker since summer of 1935. No diarrhoea or vomiting; nausea first thing in the morning; anorexia during last 2-3 months. Loss of weight during same period.

*Examination.*—General pigmentation, most marked in flexures, elbows, axillæ, and particularly in popliteal regions; also over clavicles; not much pigmentation in mouth. Blood pressure 89/66. Otherwise normal. Radiography: calcified opacities at right base but no infiltration elsewhere; no suprarenal shadows.

*Progress.*—She was treated with 15 g. salt in capsules daily, from Jan. 11th, and rapidly began to feel stronger; her appetite much improved, and the improvement continued until discharge from hospital on 15 g. of salt daily on Feb. 15th. There was no striking alteration in pigmentation, though the patient and her husband both thought she was lighter in colour. Her weight had increased by 2½ lb. during the period in hospital.

*Chemical findings* (Table II.).—After a week's treatment with salt the serum had returned to nearly normal composition, except for a marked fall in serum protein from 6.6 to 5.2 per cent., indicating increase of blood volume. A fortnight later, sodium and chlorine remained nearly normal, and serum proteins had now risen to 6.1 per cent., suggesting synthesis of fresh protein.

Cases 7 and 8 are of interest because they were admitted to hospital for other complaints, and it was not until chemical examination of the blood had been carried out that the diagnosis was made. Case 7 was thought at first to be some form of neurotic vomiting and Case 8 was regarded as carcinoma of stomach. Case 7 showed no abnormal pigmentation, and in Case 8 the pigmentation was slight and unusual in distribution.

CASE 7.—The patient, a woman of 42, a housewife, was admitted to Lewisham Hospital on Jan. 17th, 1936, complaining of vomiting. For about five weeks she had taken almost no food. There was no diarrhoea. No note was made as to loss of weight.

*On examination* nothing abnormal was found except feeble heart sounds and a trace of albuminuria, but it was not until Jan. 29th that the blood pressure was measured and found to be only 60/40. The possibility of Addison's disease was considered, and a specimen of blood taken the same day showed the typical changes to a very marked degree: treatment with cortical extract and saline was started but the patient died on Jan. 30th. No pigmentation, except for large "freckles" on face and a small pigmented patch on right shin, was found; and the patient had had both of these as long as she could remember.

*Post-mortem examination* showed old calcified tuberculosis at the right apex, but no suggestion of any recent activity. The left suprarenal could not be found and the right was very doubtfully recognised as a small piece of tissue about 1.5 cm. across and 3 mm. thick. The kidneys (right 150 g.; left 130 g.) were very engorged, and capsule was slightly adherent; cortex was well defined and of normal thickness.

*Histological examination* (Dr. W. G. Barnard).—Right suprarenal: normal medulla, and chronic inflammatory infiltration of scanty remains of degenerate cortex; degenerate cortical adenomata. Left suprarenal: tissues round upper pole of left kidney showed a fragment of almost completely fibrotic cortex of adrenal. There was practically no normal cortex in the suprarenal sections, the recognisable cortical cells being all degenerate. Kidney: small foci of chronic inflammatory infiltration in cortex

† Mg. 2.0 (1.7).

‡ Mg. 2.5 (2.1).

of greatly congested kidney. Dr. Barnard states that in his opinion the kidney lesions were very slight and very recent and unlikely to produce any symptoms.

*Chemical findings* (Table II.).—The most striking finding was the very high blood-urea (160 mg. per 100 c.cm.); this, in combination with the presence of casts and protein in the urine, made the diagnosis of uræmia a possible one. Against this diagnosis, the fall in the sodium was more marked than that in the chlorine, and the potassium was higher than usually met with in uræmia, although very high values are sometimes met with in this condition.

CASE 8.—A retired schoolmaster, aged 66, was admitted to Charing Cross Hospital on May 10th, 1935, complaining of loss of strength and weight for ten weeks. During the last six weeks he had been in bed suffering from anorexia and vomiting (but no diarrhoea), and had lost 1½ st. Neither he nor his wife had noticed any change in colour.

*Examination*.—A rather wasted elderly man: rather dark complexion, but not outside normal limits. There were patches of pigmentation over spines of each scapula and round the anus. No pigmentation in mouth and none noticed over flexures. No other abnormality except blood pressure of 80/60 on admission and 60/40 on May 23rd. The patient gradually sank and died on May 24th, in spite of treatment with cortical extract and saline.

*Post-mortem examination* revealed tuberculous scarring of upper lobes of both lungs. Both adrenals showed advanced tuberculous caseation, and there was a small patch of tuberculous infection in right kidney.

*Chemical findings* (Table II.).—The typical fall in sodium and rise in potassium and urea were found in this case.

#### CHEMICAL METHODS USED

All observations were made on venous blood collected anaerobically without stasis, and serum was separated without CO<sub>2</sub> loss, usually within 1½ hours after the blood was taken, and without exception within 3 hours.

*Na*.—Uranyl gravimetric method (Butler and Tutill).

*K*.—Cobaltinitrite precipitation, direct on serum (Kramer and Tisdall).||

*Ca*.—Precipitated as oxalate, and washed by Clark and Collip's method.

*Mg*.—Colorimetric, magnesium ammonium phosphate precipitate.

*Cl*.—Open Carius method (Van Slyke and Sendroy).

*P*.—Colorimetric using stannous chloride as reducing agent (Kuttner and Lichenstein).

*HCO<sub>3</sub>*.—CO<sub>2</sub> capacity method, using Van Slyke volumetric apparatus.

*Protein*.—Microkjeldahl (Howe).

*Urea*.—Colorimetric micro-urease (Archer and Robb).

#### CHANGES IN THE SERUM CONSTITUENTS ON TREATMENT

*Sodium*.—In all cases under first observation the sodium content of the serum was definitely below normal, and in three cases (Nos. 3, 5, and 6) out of four in which salt was given in adequate dosage it returned to more or less normal values on treatment with salt. In one case (No. 3) salt alone was unable to maintain the normal level, and small doses of cortical extract had to be employed (cf. Harrop, Soffer, Nicholson, and Strauss).<sup>15</sup> In two cases (Nos. 1 and 2) there was no appreciable alteration in the sodium under treatment with salt. In no case was the serum sodium altered significantly by treatment with cortical extract without added salt, though it should be pointed out that, with the exception of Case 2, none of the cases in the present series received more than 6 c.cm. cortical extract per day without salt. As has been pointed out by Stahl, Atchley, and Loeb<sup>16</sup> there is no correlation between

the fall in the serum sodium and the retention of nitrogen in the blood, though the two changes are frequently encountered simultaneously.

*Chlorine*.—In general, serum chlorine figures ran very closely parallel to the sodium figures though the fall in the sodium is usually more striking than the fall in the chlorine. Harrop, Soffer, Nicholson, and Strauss<sup>15</sup> have shown that if sodium salts other than the chloride are used in treatment it is possible to have a high sodium content with a low chlorine, and they suggest that hydration is governed more by the sodium ion than the chlorine ion. None of the patients in this series was treated with any salt of sodium other than the chloride.

The *potassium* content of serum in all untreated cases was above normal, and in general returned to normal before the sodium showed any alteration. Similarly, in Cases 2 and 3 on cessation of treatment with cortical extract the serum potassium rose before there was any sign of fall in the serum sodium.

The *calcium* was usually within normal limits, but in Case 2, where there was marked plasma dilution, it fell from 11.4 to 8.6 mg. per 100 c.cm. as the serum protein fell from 6.5 to 5.0 per cent. In Case 7 it was abnormally high.

*Magnesium* was not estimated in the majority of cases: in the two where it was, it was within normal limits. In the majority of reported cases no estimation of magnesium has been recorded, so it is not clear whether a marked rise of serum magnesium such as is observed in adrenalectomised animals is to be expected.

The serum *bicarbonate* tended to be on the low side of normal, though not very strikingly so. In three cases (Nos. 1, 2, and 6) it rose appreciably under treatment, and, in fact, in Case 2 what rise there was in serum sodium was entirely accounted for as bicarbonate, the serum chlorine being essentially unchanged. In this case also, the bicarbonate fell to a subnormal value when cortical extract was omitted.

*Inorganic phosphate* was normal except in Case 6, where it was rather high and remained high, and Case 7, where it was very high. In Case 2 it came down to quite low values under treatment with cortical extract, and rose again when specific treatment was omitted.

The change in *serum protein* was followed in five cases. In two of these (Nos. 2 and 6) there was evidence of marked plasma dilution under treatment, in the former with salt plus cortical extract, and in the latter with salt alone. In Cases 1 and 5 there was no marked change in serum protein under treatment with cortical extract or salt, although patients showed clinical improvement. It is of interest in this connexion that Brown and Roth<sup>17</sup> found the blood volume normal in nine cases of Addison's disease. Brown and Roth however, in one case which "improved markedly," found a rise in blood volume from 81 to 97 c.cm. per kg. Case 6 is of particular interest: the serum protein fell from 6.5 to 5.17 per cent. after one week's treatment with salt, and then increased again to 6.1 per cent. after a further 2½ weeks. As the hæmoglobin, which at first was 90 per cent., remained about the 65 per cent. level during this period, and the patient was gaining weight, this suggests a rapid synthesis of new serum protein.

In general the hæmoglobin values yield evidence of blood dilution similar to that given by the serum protein figures.

The blood-*urea* was above normal before treatment in all of the cases described in this paper, and

|| Watchorn and McCance<sup>14</sup> have shown that in normal blood there is no significant escape of potassium from the cells for about 7 hours: even with the low osmotic pressure of plasma in Addison's disease it seems unlikely that much change will take place in 3 hours.

returned to normal in Cases 1 and 2 with cortical extract alone, in Cases 5 and 6 with salt alone, and in Case 3 with salt plus cortical extract. In Cases 1 and 3 salt alone was not sufficient to keep the blood-urea within normal limits, but in Case 3 it began to return towards normal when small doses of cortical

## A NEW DYSTROPHY OF THE FIFTH FINGER

By A. ROBINSON THOMAS, B.Chir. Camb., D.M.R.E.  
SECOND ASSISTANT RADIOLOGIST AT ST. GEORGE'S HOSPITAL;  
RADIOLOGIST TO THE BELGRAVE HOSPITAL FOR CHILDREN,  
LONDON, AND TO THE CHILDREN'S HOSPITAL, LUTON

So much has been written, so much surmised, and so much elucidated about bone disease in recent years that one hesitates to add to the superabundant articles on this subject. Three recent and similar cases, however, have prompted me to describe and classify yet another bone dystrophy, which appears to affect only the terminal phalanx of the little finger.

This condition was first reported by Kirner<sup>1</sup>; Kohler,<sup>2</sup> in referring to it as an extraordinary case, says the cause of the condition is still unknown.

It is described by Kirner as an unusual appearance of the terminal phalanx of the fifth finger on either side occurring in a girl of 13, of healthy stock and with a normal childhood, whose mother had noticed a curvature of the terminal phalanges for about two months. The child was a pale, slender girl of ordinary mentality. The ends of her little fingers appeared curved, and also shorter than normal. The other phalanges were normal. Skiagrams of the affected fingers showed that on each side the epiphysis for the terminal phalanx was normal, while the shaft showed some loss of bone structure, sclerosis, and a curvature towards the palmar aspect.

A case with a similar radiological appearance is described by Brailsford<sup>3</sup> as an unusual but characteristic pathological change in the terminal phalanx of the fifth finger. A girl, aged 9, for twelve months had noticed swelling at the end of her little finger. The surgeon who examined the finger sent her to be radiographed with a provisional diagnosis of enchondroma. There was no evidence of injury.

### CASE REPORTS

In the last few months three cases of similar appearance have come to the writer's knowledge.

**CASE 1.**—A girl, aged 11, the mother's third child, all the other children being normal. She had a normal birth and no instruments were used. The mother noticed 8-9 months ago curving of the tips of the fifth fingers, but the child complained of no pain. There was no tenderness at this stage on physical examination. There was no history of any similar deformity in the family, and the remainder of the fingers and toes appeared to be normal.

The skiagrams showed an unusual appearance of the terminal phalanx of the fifth finger on each hand. There was sclerosis of the epiphysis together with

elongation and curvature of the shaft of the phalanx. The bone of the shaft had lost in some degree its normal structure.

**CASE 2.**—A girl, aged 12, one of a family of five, all of whom were alive and well. Her birth was normal and no instruments were used. She was fair, mentally alert, but perhaps rather small in size for her age. Her mother had noticed that the tips of the child's little fingers had been bent over for some time. About 10 days before the examination the child fell over while doing physical exercises at school and hurt her finger, and the mother brought her to hospital preparatory to making a case against the school authorities.

A skiagram of the fifth finger of the left hand showed that there was elongation and curving of the shaft of the terminal phalanx, the bone appearing to have lost, in some degree, its normal structure. The epiphysis did not appear to be involved. The remainder of the bones of the hands and feet showed no abnormality.

**CASE 3.**—A girl, aged 8 years, the fourth of the family, the others showing no abnormality. This child had been born a month prematurely, and was rather small for her age. Mentally she was definitely dull and had rather a mongoloid appearance. Her mother had noticed 4 years before that the tips of the little fingers were curving, and had drawn the school doctor's attention to this, but no further steps had been taken.

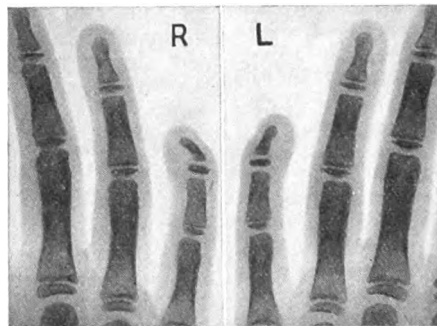

A skiagram showed a bilateral curving of the terminal phalanx of the fifth finger on either side, that on the right being most affected. There was definite loss of the normal bone structure of the shaft of each phalanx.

The epiphyses did not appear to be affected. The remainder of the fingers and toes were normal.

### DISCUSSION

The almost identical radiological appearance in these cases makes it probable that the ætiology in all of them is the same. Kohler reports that the nature of the condition is unknown, while Brailsford classifies it as a characteristic pathological change, but commits himself no further. After consideration and reflection, however, it seems probable that this lesion is due to an osteochondritis. In all the cases the shaft of the phalanx, in addition to being bent, shows a definite loss of its normal bone structure, while in one case the epiphysis is definitely sclerosed; osteochondritis is the only known condition which would fit in these appearances. The phalanx takes on the curved "taloned" effect because in its probable earlier state of osteoporosis it has been unduly affected by the action of the flexor muscles, which are stronger than the extensors, with a resultant palmar bowing. Furthermore, all the recorded cases have been of an age when osteochondritis is most common.

These cases have some medico-legal interest, for in at least one of them the mother of the patient had

CASE 1

CASE 2

CASE 3

intended to sue the authorities of the school, alleging that the unusual appearance of the child's finger was due to some accident that had happened in the gymnasium.

## SUMMARY

What is probably another manifestation of osteochondritis involving the terminal phalanx of the little finger is here described in 3 girls. All cases hitherto reported have appeared in female children aged 8-13. In 3 cases it was bilateral and in 2 unilateral.

## ABSCESS OF THE SPINAL CORD

By R. MILNES WALKER, M.S. Lond.

SURGEON TO THE ROYAL HOSPITAL, WOLVERHAMPTON; AND

S. C. DYKE, F.R.C.P. Lond.

PATHOLOGIST TO THE HOSPITAL

MOST writers on the subject of abscesses of the spinal cord have commented on the rarity of the condition. Woltman and Adson<sup>1</sup> made a searching review of articles on the subject in 1926, and were able to find records of only 29 cases; to these they added a further case of their own, and another has since been reported.<sup>2</sup>

The commonest causes of such an abscess were found by Woltman and Adson to be injuries or diseases of the spine, and chronic inflammatory diseases of the lungs. In one case it was associated with a meningocele which became infected, and in another there was a dermoid cyst over the cervical spine from which infection spread to the spinal cord. In only 2 cases is recovery recorded, in both the abscess being drained by operation; in the first the condition was associated with a fractured spine and a permanent paraplegia persisted, the lesion being in the twelfth dorsal region; Woltman and Adson's case, in which the abscess apparently resulted from suppuration at the site of a previous acute myelitis, made a complete functional recovery.

A girl, aged 3, was admitted to the Royal Hospital, Wolverhampton, on Oct. 29th, 1934, under Dr. J. H. Sheldon. There was a history of illness for the past 12 months, consisting of attacks of headache and vomiting. At first these attacks occurred at intervals of 2-3 weeks and lasted 12-24 hours, but during the previous month the attacks had become much more frequent, occurring nearly every other day. During these attacks she lost the use of her legs and her mother stated that she screamed with pain in her back when the pram was wheeled over rough stones; in between the attacks she was able to walk quite well. For the last week the headache had been more severe and persistent, the vomiting had occurred daily, and she complained of aching pains all over her body, and had quite lost the use of her legs. There was no aural discharge, and examination of the chest and abdomen was negative. There was no history of respiratory infection or disease of the ears, and she had been apparently quite well and normally developed until the onset of these attacks.

On admission her temperature was 101.4° F., pulse-rate 140, and respirations 32. She looked flushed and was somewhat wasted, the face having a drawn expression. There was much rigidity of the neck, the head being retracted, and a positive Kernig's sign. Any movement of the legs, which were spastic, appeared to cause her

considerable distress. The reflexes in the upper limbs were normal, but the knee- and ankle-jerks were increased, and a positive Babinski's sign was present on both sides. No sensory changes could be detected.

Lumbar puncture was performed and thick blood-stained fluid withdrawn. On microscopic examination this showed pus cells and morphological pneumococci; a diagnosis of pneumococcal meningitis was made and one of us (S. C. D.) was asked to see the patient with a view to treating her with serum. The history did not suggest the usual type of pneumococcal meningitis and the changes in the reflexes in the lower limbs were an unusual feature. Serum was withheld; subsequent investigation of the pneumococcus showed it to be of neither Type I. nor II., and the question of serum treatment was therefore allowed to lapse. A tentative diagnosis was made of abscess somewhere in the central nervous system.

At this stage the sister in charge of the ward drew attention to a small dimple over the lower lumbar vertebrae, with a single hair growing from it, which had previously escaped notice. The surrounding skin was still stained with the iodine applied in preparation for the lumbar puncture, and the dimple was difficult to see; a radiogram, however, showed spina bifida, the neural arches of the 4th and 5th lumbar vertebrae being incomplete.

On Nov. 1st lumbar puncture was repeated; 10 c.cm. of foul-smelling frankly purulent fluid were first obtained; as the needle was being withdrawn a further 4 c.cm. of fluid of quite different appearance flowed from it. This latter specimen was turbid but not frankly purulent, and odourless. Both specimens of fluid on culture gave a growth of pneumococci and coliform bacilli but the chemical examination revealed striking differences. Whereas the purulent foul-smelling fluid gave a protein content over 0.50 per cent. and chlorides to the extent of only 0.56 per cent., the turbid odourless fluid had only 0.2 per cent. protein and 0.67 per cent. chlorides. The differences between the two specimens appeared significant and gave rise to the impression that a localised collection of purulent fluid lying somewhere within the theca and requiring drainage had been tapped. Cisternal puncture was also performed on the same day and 4 c.cm. of turbid cerebro-spinal fluid was withdrawn; films of this showed pus cells and mixed organisms, and the cultures yielded pneumococci, staphylococci, and coliform bacilli. Lumbar puncture was performed repeatedly during the subsequent days but the general condition showed no improvement and it was decided to explore the vertebral canal.

On Nov. 7th, 1934, under general anaesthesia, the spinous process of the 3rd lumbar vertebra and portions of the laminae of the 3rd, 4th, and 5th were removed. A thick fibrotic stalk was seen to spread down from the subcutaneous tissues to the dura mater with which it was continuous, but this stalk appeared solid and it was not definitely ascertained whether it had any connexion with the small dimple of the skin. The dura, which was thickened and reddened, was incised; a small amount of turbid cerebro-spinal fluid escaped, but no pus was found such as had been aspirated previously, and the wound was therefore closed. A microscopic section across a portion of the fibrous stalk showed that it had a very small lumen, lined by squamous epithelium.

As was to be expected, no immediate improvement in the general condition followed the operation, but during the subsequent 3 weeks the temperature gradually subsided, and the pulse-rate dropped to the region of 120. The rigidity of the lower limbs, however, became more severe. Cisternal puncture was carried out on Nov. 13th, 20th, and 27th; the specimen on the latter date was still turbid but gave no growth on incubation. The cells were much fewer, being now 375 per c.mm., all pus cells. Lumbar puncture fluid on the same date yielded pneumococci and abundant pus cells, being definitely purulent. On Nov. 30th the patient's general condition was considerably improved, but the symptoms in the lower limbs continued. At no time during the illness did she have any incontinence of urine or faeces.

On Nov. 30th the spinal canal was again explored under a general anaesthetic. Before making the incision

a needle was inserted and thick pus withdrawn; the needle was left in situ and its track followed. On opening the dura the spinal cord appeared swollen and congested, and the needle was penetrating its substance, but on retracting the cord to one side it was found that the point of the needle did not project on the anterior surface. The needle was therefore withdrawn and the cord incised in the midline posteriorly. About 12 c.cm. of thick pus then escaped; this was lying in a cavity in the centre of the cord, the cavity being 1 cm. in diameter. It extended up the spinal cord beyond the limit of the incision in the dura, and a probe easily passed up a further 5 cm., the upper limit of the cavity not being reached. A small rubber drainage-tube was then inserted into the cavity in the spinal cord, and a corrugated rubber drain placed into the opening in the dura, these being brought out through the wound which was sutured above them.

After the operation there was slow but steady improvement in the general condition, but the spasticity of the lower limbs persisted. The wound continued to discharge pus and cerebro-spinal fluid for about 3 weeks, after which it rapidly closed to a small sinus.

On cisternal puncture on Dec. 26th, clear and colourless cerebro-spinal fluid was withdrawn; this yielded no pathogenic organisms, and only 15 cells per c.mm., these being all lymphocytes.

She was discharged from hospital on Jan. 25th, 1936, when there was still considerable spasticity of the lower limbs, but the wound in the back was completely healed except for a small superficial ulcer. At the time of leaving hospital she had been able to walk with assistance, but 3 months later the spasticity had entirely disappeared and she walked quite normally. The wound in the back was healed, and there were no abnormal physical signs. The wound broke down 9 months later and discharged some pus for a few days, after which it closed again and has since remained closed.

In April, 1936, she had no headaches, could enjoy herself playing with other children, and was mentally normal for her age.

#### DISCUSSION

In the case here recorded it is impossible to give a definite opinion on the cause of the abscess, but it seems probable that, associated with spina bifida, there was a sinus analogous to a coccygeal sinus but situated in the lumbar region, leading down to the dura, and that infection had spread by this route from the skin to the dura and spinal cord. A remarkable feature is the duration of the symptoms; it

seems probable that a localised infection of the meninges in the neighbourhood of the sinus had existed for at least a year before the onset of the symptoms for which the patient was admitted to hospital; these symptoms appear to have been associated with generalised spread of the meningeal inflammation.

At the first lumbar puncture on Nov. 1st the purulent fluid withdrawn showed only 0.56 per cent. of chloride; this represents a gross diminution. The turbid fluid withdrawn at the same puncture and which represented an actual sample of the free cerebro-spinal fluid showed chlorides to the extent of 0.67 per cent.; this was evidence of a separate source for these two samples. A level of 0.67 per cent. is near that usually met with early in a severe meningitis to which a fatal issue may be expected. On Nov. 28th, 3 weeks after the first operation, fluid withdrawn both by lumbar and cisternal puncture showed a level of 0.68 per cent. indicating that there had been no further advance in the inflammation of the meninges. On Dec. 28th, 4 weeks after the second operation when the general condition was improved, the chloride level was 0.71 per cent., and by Jan. 1st it had risen to 0.74; at this date except for a protein content of 0.180 per cent. the fluid was in all respects normal.

The chronicity of the meningitis is a point of interest, for the course was quite different from that ordinarily seen in pneumococcal meningitis. This may have been due either to the establishment of some degree of immunity by the patient or to relative avirulence of the organism; these aspects of the matter were not subjected to investigation. It should be emphasised that the whole picture both from the clinical and laboratory standpoints was entirely different from that met with in true pneumococcal meningitis; this case should not, therefore, be included among the very rare examples of recovery from that condition.

The thanks of the authors are due to Dr. J. H. Sheldon for access to the patient and to the records of the case.

## REVIEWS AND NOTICES OF BOOKS

### *Nouvelle pratique dermatologique*

By Drs. J. DARIER, R. SABOURAUD, H. GOUGEROT, G. MILIAN, L. M. PAUTRIER, P. RAVAUT, A. SÉZARY, and CLEMENT SIMON. Paris: Masson et Cie. 1936. In eight volumes. Inclusive price in advance, Fr.2000.

THIS treatise, of which five volumes have now been issued, is a most comprehensive and authoritative compilation. There are no less than 7350 pages of text in the volumes already published and a collection of illustrations in colour and half-tone reaching the immense total of 2425. The responsible editors, who constitute the directorate, are named above; to their number must be added a list of 80 contributors, each distinguished for original research or particular experience in the special subject allotted to him. An index is to follow in the eighth.

The first volume deals with cutaneous anatomy and physiology, general histology—profusely illustrated by A. Civatte from the well-known collection at the St. Louis Hospital—etiology, pathology, semiology,

diagnosis, and general therapy. The four authors in intimate collaboration here are Darier, Civatte, C. Flandin, and A. Tzanck. The last named is responsible for the article on aetiology, and according to Darier has formulated therein some new conceptions which are likely to influence the future development of our views on cutaneous reactions in general. There must be a more careful discrimination between what is meant by intolerance and intoxication. The two terms are frequently confused even by accepted authorities, some of whom appear moreover to have no clear conception of the difference between real and apparent causation, and are apt to overlook or ignore the multiplicity of factors usually operating in the production of even simple reactions. A brief glance at the table of causes on pp. 367–369 in which causes are divided into (a) "Efficientes," which we might perhaps translate as evocative, and (b) Pre-disposing, and their superimposition on pp. 466–469 in the form of a "Tableau Synoptique," will suggest how complex and contingent are modern conceptions of aetiology. An entirely new departure is the section

of 31 pages given to the examination of a patient suffering from a skin affection (pp. 554-585). The same ideas are here emphasised. Itching, for instance, is stated to be a symptom of *intolerance*; its absence, as in syphilis or tuberculosis, suggests *intoxication*. The meaning of pruritus and the help it can afford in the diagnosis of an obscure metabolic affection are analysed in the greatest detail and this section will repay careful study by any physician faced with an unusually difficult problem in dermatology.

The digestive apparatus from the tongue downwards, the gums and teeth, the mobility of the soft palate, the state of the lymph glands, the liver and pancreas may all have a bearing on the course or genesis of the affection studied. The examination of lungs and mediastinum and the kidneys and other organs by appropriate measures are all points which the physician is not likely to neglect, and a résumé of appropriate clinical laboratory investigations is given. All that is known on the association of the neuro-vegetative and endocrine systems in cutaneous disorders and diseases is also set out and this section demonstrates how extensive must be the equipment of the modern dermatologist. The volume ends with a dissertation on general therapy.

Vol. II., for which ten authors are responsible, begins with a profusely illustrated study of the diseases caused by animal parasites. The acari infesting the cat, dog, horse, and sheep differ both in their morphology and symptomatology from the human species and are separately considered. The chapters on ring-worm and the mycelial infections of the human skin are by Sabouraud, whose classical work "*Les Teignes*," published many years ago, has become the inspiration for those later studies of blasto- and sporo-trichosis, mycetoma (Madura foot), moniliasis, and other mycelial diseases which are here fully described and illustrated, mostly by the original investigators themselves. The concluding third of this volume is devoted to syphilis, and has been written by G. Milian. Of particular interest is the plea he makes, in his section on treatment, for the administration of larger doses of the salvarsan group. He bases his argument on the assumption that the lethal dose for a man of average weight is 10 grammes and that the injection of small doses at the relatively long interval of a week is the cause of most of the cases of so-called refractory or salvarsan-fast syphilis, and the other undesirable sequelæ occasionally met with.

Vol. III. carries the dissertation of syphilis to the later stages and discusses the regional varieties in complete detail. Stress is laid on the value of the CO<sub>2</sub> pencil treatment of leukoplakia of the tongue and cheeks—one of the most intractable of all luetic affections. It is suggested that a minimum of 1 minute exposure with a 1 pound pressure through a thin layer of gauze is an efficient dose. Every aspect of the disease, on which the author may be regarded as an authority worthy to succeed Fournier, is dealt with in the succeeding pages, which conclude with an article describing the various tropical varieties encountered in Asia and Africa. Pian—frambœsia or yaws—is next discussed, and studies on leishmaniasis and Delhi sore are well illustrated. The long treatise on cutaneous tuberculosis and tuberculides, by Pautrier, one of the most careful workers and authors in this domain, provides a most important contribution to the literature of the subject and one that will be widely studied and quoted. Preference is given to the tuberculous as opposed to the streptococcal and other theories

in the genesis of lupus erythematosus. Leprosy is also described in this volume. Milian has made himself responsible for the articles in Vol. IV. on the streptococoides, in which he includes impetigo, and the vexed ætiological question of the so-called acrodermatitis continua. Common associations of streptococcal infections, such as scabies and ringworm, are separately discussed and illustrated. Sabouraud gives an account of furunculosis and syccosis barbæ et generalisata under the heading of "*folliculites*," and reprints his well-known diagrams which did so much to establish an ordered classification among staphylococcal infections of the skin. The dermatoses due to ultramicroscopic and filtrable viruses include the common wart and its varieties, molluscum contagiosum, certain papillomata, and the herpetic group. These are discussed in detail and well illustrated under the combined authorship of Paul Ravaut and Marcel Ferrand. This section is followed by a useful contribution on the eruptive fevers, including "*fourth*" disease, a name first suggested by Dukes of Rugby in 1900, and to this day a somewhat doubtful entity (rubéole scarlatineuse). A most interesting section by Milian worthy of close study is that given to the drug eruptions, which nowadays are more often seen as new medicaments are introduced. Their variety has necessitated a complex tabulation according to the morphology of the lesions resulting. Thus we may have eczematous, urticarial, polymorphic-erythematous, erythematous-squamous, nodular, acneform, purpuric, and so forth—veritable equivalents and competitors both in number and variety of the dermatoses due to infective and metabolic causes. In view of its frequent incorporation in proprietary laxatives, phenolphthalein dermatitis receives special mention and illustration. Equally worthy of note are the arsenobenzol, thallium, and barbitone eruptions. The whole of this large section has been carefully compiled and generously illustrated, and is probably the most complete of its kind yet published.

In comparison with the detailed discussion of the foregoing, urticaria, one of the commonest and most troublesome of all skin manifestations, receives but scant consideration (C. Flandin and others, pp. 1-35, Vol. V.). Its treatment by specific and non-specific desensitisation, by injection of sodium thiosulphate (Ravaut) and calcium are duly tabulated. "*Eczema*" is retained as a nosological entity and is defined as a "*vesicular dermo-epidermal reaction which can be caused in predisposed subjects by numberless pathogenic factors habitually innocuous to the skin of a normal individual*" (A. Sézary and A. Horowitz). The various clinical forms are illustrated and discussed in detail, and a separate section is given to the eczema of infants. The "*eczematides*," a name first suggested by Darier to cover a group of eczema-like eruptions of erythematous-squamous type, such as our so-called "*flannel rash*"—a seborrhœic manifestation—are considered by Sézary in a separate chapter. The name is not much used outside France, and has so far not received general recognition as a separate entity. That much disputed condition dysidrosis of the hands and feet is also discussed in a separate chapter. The conclusions as regard its ætiology favour a mycelial origin, but are on the whole non-committal. Even this disease has not escaped the suspicion, so prevalent in France, of a congenital syphilitic basis (Milian). This volume also deals with the various forms of prurigo and pruritic diseases of uncertain causation. The chapter on Raynaud's syndrome by Nicolas and Ravaut will be studied with special interest in view of the

recent advances in its therapy by surgical means, periarterial sympathectomy, ganglionectomy, and so forth. The new disease, erythrocyanosis cruris puellarum, has been dignified with a special chapter, and its aetiology clarified so far as that is possible. The consideration of a large number of vascular abnormalities, including purpura, leg ulcers, gangrene, and conditions associated with blood diseases follow in detail. An extensive consideration of psychopathic dermatoses, newly classified by Clement Simon, merits special study as a sign of the times.

We await with keen interest the completion of this great work.

### Fluorescence Analysis in Ultra-violet Light

Second edition. By J. A. RADLEY, M.Sc., A.I.C., and JULIUS GRANT, Ph.D., M.Sc., F.I.C. London: Chapman and Hall Ltd. Pp. 326. 21s.

FLUORESCENCE analysis in ultra-violet light is by no means new, but it is only fairly recently that it has come into its own. Like most applications of physical method to other branches of science, it suffered at first from the unjustified optimism of those interested in it, but its practical value is now recognised. Moreover, there are now available light sources which emit ultra-violet light sufficient in quantity and quality for most purposes of fluorescence analysis.

This book opens with a theoretical account of electro-magnetic waves, embodying a useful chart which shows the range of radiations at present recognised. An account follows of the methods available for the production of ultra-violet light, as this relatively short range is mostly used as the exciting radiation in fluorescence analysis. Filters or other methods of isolating short ranges of wavelengths are then described. Most attention is given to the mercury arc as a source of light; other sources that are in some respects and in some circumstances more satisfactory are not so fully described. Measurement of intensity of radiation receives inadequate notice; it is admittedly a difficult branch of work but its importance should have been emphasised. Some definite expression of opinion by the authors on the methods available would have been welcome; the mere recapitulation of the results of others is not enough. Methods and technique are described at some length, but the short section dealing with microscopy is both inadequate and misleading. It is difficult to see how anyone starting fluorescence microscopy, and such work is becoming increasingly important, could regard the information provided as satisfactory even for an introduction, and in a future edition considerably more space ought to be allocated to this aspect of the subject. The book is well produced and illustrated.

### The Silver Fleece

An Autobiography. By ROBERT COLLIS. London: Thomas Nelson and Sons, Ltd. 1936. Pp. 290. 15s.

Dr. Collis is an Irishman still on the right side of forty who wears his heart on his sleeve. Born in Ireland, he was bred at an English public school which never succeeded in moulding him to that conventional pattern which has excited so much favourable and unfavourable criticism. Though just old enough to join the army during the war, he missed active service abroad, and his pacifism is founded not on personal experience of the horrors of war

but on the conviction that wars are terrible things and should not occur. He has played international "rugger," spent a year at Yale and, as a boy, saw at first hand something of the trouble in Ireland. Apart from these, his experiences have not been exceptional, but he contrives to make them interesting without being melodramatic, except perhaps when writing of sick children in hospitals. Dr. Collis is a mezzo-brow, neither high nor low. He writes unaffectedly, and one is left with the impression that few of his contemporaries could have made of their memoirs such good reading. The decorations, by T. G. Wilson, are an asset.

### Orthopædic Surgery

Second edition. By WALTER MERCER, M.B., Ch.B., F.R.C.S., F.R.S. Edin., Assistant Surgeon to the Royal Infirmary, Edinburgh. London: Edward Arnold and Co. 1936. Pp. 906. 40s.

IN its second edition this book is very much enlarged. It has some 200 extra pages and 37 additional illustrations. Mr. Mercer has added considerably to the part dealing with congenital deformities and has included two new chapters on circulatory disturbances of the extremities and manipulative surgery.

By far the best part of the book is the first which deals with congenital deformities and diseases of bone, including tubercle, though there are some important omissions, for example, of any picture of the Denis Browne splint for the treatment of congenital equino-varus. The section on bone tubercle is amply illustrated and contains a fair and concise résumé of recent work, including the important researches of Seddon and Butler on Pott's paraplegia. As a whole when the author deals with subjects of general surgical interest the book is good, but when he ceases to be a general surgeon with an orthopædic bent and speaks about pure orthopædics the balance is less sure. In his anxiety to include new matter he has failed to bring up to date some of the sections in the original, for instance the description of the treatment of pes cavus. The review of flat-foot, a subject of profound interest to orthopædic surgeons, is inadequate and no mention is made of the association of rigid flat-foot with focal sepsis.

In spite of these defects this book is undoubtedly a useful one for the third-year student. Mr. Mercer has taken so much trouble that it might almost be regarded as a dictionary of terms used by surgeons in connexion with bone, joint, muscle, circulatory, and nerve conditions. If it does not succeed in stimulating the interest of a student in orthopædic surgery, this is because it does not lay sufficient emphasis upon the general principles of orthopædic work or stress the differences in outlook between the orthopædic and general surgeon. The eradication of disease and the correction of deformity is not the main interest of the orthopædic surgeon. His chief concern is to restore or improve function. He may often advise against the correction of a deformity, or, conversely, in order to improve function he may actually create a deformity. It is this fascinating aspect of orthopædic surgery to which less than justice is done in this otherwise satisfactory book.

ONE FLAG DAY.—The possibility of one big flag day for all the London hospitals is under consideration. This would take the place of the 66 hospital flag days at present held every year in London and the suburbs.

LONDON: SATURDAY, JUNE 20, 1936

## BACTERIAL EVOLUTION

RELATIONSHIPS, more or less remote, between various species of bacteria have long been recognised, and schemes of classification have been introduced which seek to indicate something more than degrees of similarity or dissimilarity. The analysis of structure offers a very elementary separation of bacterial types; physiological characters, determined with varying degrees of crudity, have been the guides to the nicer differentiation of species. Mr. KNIGHT, in a monograph on Bacterial Nutrition,<sup>1</sup> has made an extensive survey of the more exactly determined physiology of bacteria, and has tried to coördinate his observations by the help of an evolutionary scheme for the schizomycetes. The first part of his report surveys the facts; the second is devoted to coördination of observation; and the third to the mechanism of nutritional variation.

Bacteria may be arranged in a scale of increasing complexity of nutritional requirements. At one end are organisms with a wide range of synthetic ability, capable of obtaining energy and materials for the synthesis of their protoplasm from the simplest chemical compounds; such are the photosynthetic bacteria, resembling the green plants in obtaining energy mainly from light, and certain chemosynthetic bacteria, whose production of energy depends entirely on the chemical reactions they initiate. Intermediate between these organisms, utilising inorganic matter, and the bacteria which derive energy by the breakdown of complex carbon compounds, are bacteria which absorb CO<sub>2</sub> or simple organic compounds for their carbon (oxidising hydrogen for the purpose), or utilise CO, CH<sub>4</sub>, or similar hydrocarbon as a source both of carbon and of energy. Next in the scale of complexity come organisms like *Bacterium coli* and *Pseudomonas pyocyanea*, requiring complex carbon compounds as source of energy and carbon, but assimilating nitrogen as NH<sub>3</sub> for the synthesis of their protoplasm. *Bact. typhosum*, *dysenteriae* Shiga, *paratyphosum* A, and *Proteus vulgaris* occur as "exacting strains," requiring amino-acids for their nitrogen, from which "non-exacting" strains, utilising NH<sub>3</sub>, can be derived. They form a link between types like *Bact. coli* and those (such as the acid-fast bacilli and the diphtheria bacillus) which cannot grow unless amino-acids are present as a nitrogen source. Even among the members of a single group, however, there are differences of nutritional requirements. The acid-fast bacilli, for example, are capable of arrangement in a special series which corresponds, as in the main

series, to a progressive restriction in utilisable sources of energy and food—viz., the saprophytic acid-fast bacilli which are least fastidious, the cold-blooded, avian, and finally the human types of tubercle bacillus. John's bacillus is the most fastidious, being apparently unable to synthesise a substance, essential for its growth, that is readily supplied by the Timothy grass bacillus and the human tubercle bacillus. The increasing complexity of nutritional requirements is associated with decreasing synthetic powers, which include the capacity to synthesise essential growth substances. These substances are analogous to the vitamins of animal metabolism. They have been prepared as potent concentrates by Mr. KNIGHT and his associates, and found essential for the growth of certain bacteria. They include (a) the "sporogenes" factor, synthesised, for example, by *Bact. aertrycke* and *Aspergillus versicolor*, found in yeasts and mammalian urine, and required already formed for the growth of *Clostridium sporogenes*, *botulinum*, and *welchii*; and (b) the "staphylococcus" factor, synthesised, for example, by *Pseudomonas pyocyanea* and *Vibrio cholerae*, and essential for the growth of staphylococci and *Bacillus anthracis*. At the upper end of the scale are organisms not yet grown in synthetic media of known composition, whose special requirements are supplied by chemically indeterminate mixtures like enriched nutrient broth. The group includes the influenza bacillus with its peculiar requirements of X and V factors, the brucella organism, the streptococci, pneumococci, the meningococcus, and the gonococcus.

The series arrived at by arranging the bacterial species as briefly described is claimed to be more than a merely static classification, similar to those put forward by FISCHER and ORLA-JENSEN; it represents an evolutionary series. Mr. KNIGHT bases his arguments on the following facts. In the course of world evolution, the simpler carbon and nitrogen compounds presumably developed first; and the bacteria that first arose would presumably be those capable of utilising NH<sub>3</sub> and CO<sub>2</sub>. This explanation is too teleological to be readily acceptable, for it assumes that the most likely form of life was that best suited to generally prevailing conditions; whereas the origin of a "living" chemical process, or the development of a more complex one, seems equally likely to have been the result of a peculiar, not a general, set of conditions, which could as readily give rise to protoplasm of limited synthetic abilities as one of wide. The evolutionary process may thus have been not a restriction of simple synthetic powers, but the acquisition of wider ones. But postulating organisms like the present-day CO<sub>2</sub>- and NH<sub>3</sub>-utilising forms as the primitive type, the series following them is linked dynamically by the occurrence of strains of the same species at different nutritional levels; by the experimental adaptation of strains to different nutritional requirements; and by the poor synthetic ability<sup>2</sup> of the

<sup>1</sup> Bacterial Nutrition. Material for a Comparative Physiology of Bacteria. By B. C. J. G. Knight, M.Sc. Med. Research Council, Spec. Rep. Ser. No. 210. London: H.M. Stationery Office. 1936. Pp. 182. 3s.

<sup>2</sup> In addition, analogous evolutionary series can be formed for certain protozoa, supported in this group of organisms by correlated changes in anatomical structure.

predominantly and exclusively parasitic forms. If parasitism is regarded as a late adaptation in evolution, the characters of parasites are presumably late adaptations; and it is unlikely, as Mr. KNIGHT says, that the majority of pathogenic bacteria appear by chance in the class of organisms whose nutrient requirements are not satisfied by simple synthetic media. In the course of his survey a correlation does in fact appear between pathogenicity and differences of nutrition. Even bacteria like *Bact. typhosum*, that can be trained to utilise simple compounds, are more fastidious when first isolated from the body of a host.

The most persuasive evidence lies in the varying requirements of strains of the same species, and the demonstration that bacteria can apparently produce new enzymic systems to cope with new substrates. But this flexibility is confined to comparatively small portions of the immense scale of nutritional evolution that Mr. KNIGHT sketches. There is, however, no evidence for postulating a more complex evolutionary series, though it is improbable that this progressive loss of wide synthetic ability, together with the late acquisition of special abilities, such as the synthesis of lysins and toxins, is necessarily a true picture of an evolutionary tree; there may be regressions and wide digressions with re-entrant paths that complicate the main series beyond recognition. But the simplified picture forms a valuable groundwork upon which to build a bacterial classification; for, by the very nature of the criteria upon which carefully investigated strains are admitted to it, it remains flexible and empirical, yet with an empiricism that rests on a reasonable, though limited hypothesis. In reaching his conclusions Mr. KNIGHT provides critical reviews of the gaseous requirements of bacteria and of the various methods of study of bacterial metabolism (especially the preparation of synthetic media), the differentiation of essential food substances from accessory food substances, and the technique of "training" bacteria to grow in simple media. Hence there is much in his report which will interest the general bacteriologist, though the scheme for the practical use of the evolutionary classification that is put forward is at present applicable only in laboratories devoted to the kind of work that the author has both reviewed and furthered.

### INSULIN IN SCHIZOPHRENIA

"I HAVE known four and twenty leaders of revolts," said OGNIBEN. It is not necessary to have lived as long as OGNIBEN to have known four and twenty treatments of schizophrenia. In any survey such as HINSIE'S or MÜLLER'S one finds a lengthy catalogue even for the last decade. There are few therapeutic discoveries or fashions in medicine that are not sooner or later tried out upon the schizophrenic, who must also suffer fresh applications of the old principle that terror and shock are good for the insane, especially the apathetic insane; the method of "emotion therapy" reported in a psychiatric journal in 1930 had some points in common with the whirling chairs and the trapdoors of earlier times. The

reported success of various ways of treating schizophrenia makes impressive reading until one observes that ten or fifteen years after their introduction they are discarded. Endocrine therapy of opposite sorts (thyroidectomy, for example, as well as thyroid medication); prolonged narcosis; infusion of all manner of drugs and sera into the blood stream; the production of aseptic meningitis, leucocytosis, controllable fever; high-frequency currents and other forms of physiotherapy; extirpation of dubiously septic foci; psychotherapy of many kinds—all have had their more or less ephemeral heyday. In the last year or two gold salts have been tried by some, the induction of epileptic convulsions and the injection of cerebrolysates and cerebrotoxins by others; still another innovator has been gouging out pieces of the frontal lobe. Schizophrenia is certainly not one of the diseases given over to therapeutic nihilism, whatever people and text-books may say. Nor is it one of the diseases about the cure of which it is wrong to be sceptical. Recovery or remission happens often enough in schizophrenia under non-adventurous care to explain some of the success of new methods and to warrant caution in acclaiming them.

There is one new method of treatment that differs from its predecessors in several particulars. First, it is more deadly. Day after day, of set purpose, the patient is put in danger of his life; the treatment is not being properly carried out unless grave risks are run. Secondly, it is supported by an eminent and reputable authority, Prof. PÖTZL, in whose clinic it has been worked out; he declares it superior in its cures to every other method. Thirdly, it is reported to produce over 70 per cent. of full remissions, an unusually high figure. The method, which consists in giving huge doses of insulin, up to 190 units, so that the patient becomes comatose, with twitchings, sweating, and sometimes glottic spasm, transitory hemiplegia or epileptic fits, has been elaborated in Vienna by Dr. MANFRED SAKEL<sup>1</sup> who had earlier used hypoglycæmic shock in the treatment of drug addictions. It may be useful to consider the three points mentioned above before the method is either rejected or experimented with in this country. Its lethal risks are not an essential objection to it, any more than they were to the malarial treatment of G.P.I., but they impose upon every doctor who proposes to try the method the duty of reading the literature carefully and himself staying by the patient continuously during the hours of the daily hypoglycæmia, ready to intervene if the collapse goes too far. Dr. SAKEL'S account of what may happen makes it clear that the responsibility is a heavy one and that it should not be delegated; moreover, the treatment should never be carried out without very skilful and special nursing. The second point need not be given undue weight, for Dr. J. BERZE,<sup>2</sup> the greatest authority on schizophrenia

<sup>1</sup>Neue Behandlung der Schizophrenie, Leipzig u. Wien, Porles, 1935; Wien. med. Woch., 1934, lxxxiv., 1211, 1265, 1299, 1326, 1353, 1383, 1401; 1935, lxxxv., 35, 68, 94, 121, 152, and 179.  
<sup>2</sup>Wien. med. Woch., 1933, lxxxiii., 1365.

in Vienna, has written an article which is strongly critical of this treatment; he thinks it may do as much harm as good. The third point, the high proportion of recoveries, has been justly criticised<sup>3</sup> on the ground that it is in the early cases that Dr. SAKEL reports his 70 per cent. of full remissions after treatment; we are not told what proportion of the advanced cases got better. Everybody knows how high is the percentage of recoveries in early cases of schizophrenia quite apart from special treatment. Nor does Dr. SAKEL say for how long the patients remained under his notice afterwards; temporary and deceptive remissions are nothing out of the ordinary in schizophrenia. He could not have assessed the prognosis beforehand, because in some of his cases treatment was begun on the first or second day after admission. There is nothing in the report of Dr. SAKEL, or of his Polish imitators, to indicate that the treatment is worthless, but neither is there much at present to recommend it.

### EPIDEMIOLOGY OF WHOOPING-COUGH

THE Registrar-General's reports show that in England and Wales the deaths attributed to whooping-cough in the last completed decade, 1921-30, were rather more numerous than those debited to measles, or to scarlet fever and diphtheria combined. In subsequent years the position has been rather more favourable—both relatively and absolutely—to whooping-cough, the yearly attribution of deaths in 1931-34 being, roughly, 2400 to that disease, 3100 to measles, 2900 to diphtheria, and 700 to scarlet fever. In spite of this reduction—perhaps temporary, for the epidemic swing of such diseases makes the rate over a short period of years unreliable—we still have a number of deaths that is far from negligible and the more to be deplored in being nearly entirely concentrated on the first five years of life. The ubiquity of the disease, combined with its generally low fatality-rate, tends to make the layman rather contemptuous of this so-called childish malady, though the medical profession is well aware of its dangers. Recent experiments with *Hæmophilus pertussis* vaccines suggest that prevention may lie in that direction.<sup>4</sup> Increased knowledge, still somewhat scanty, of the epidemiology of the disease, is also likely to assist towards that end. To that knowledge a useful contribution has been made by Dr. RALPH E. WHEELER, working for the Milbank Memorial Fund.<sup>5</sup>

During the last five years there has been, Dr. WHEELER records, an annual average of 5500 deaths from whooping-cough in the United States registration area, and it ranks among the outstanding causes of mortality among children in the first two years of life, a position clearly parallel with that of this country. To study its epidemiology a rural section of New York State, with a population of 5500 persons, was chosen and a careful record of communicable disease kept there

for three years. During that period 280 cases of whooping-cough (with no deaths) were registered, 260 of them being persons under 20 years of age, giving an attack rate of 46 per 1000 person-years of exposure at these ages. Only 6 of the 260 persons attacked at ages under 20 gave a history of previous attack, which indicates a high degree of immunity. Not many of the persons in this area had escaped the disease at one time or another, for at age 20 a remembered history of manifest whooping-cough attack was given by about 80 per cent. of them. From a detailed regional and chronological analysis of the cases it is concluded that some 12 per cent. could be classified as primary cases infected by sources which could only be surmised, 14 per cent. could be reasonably attributed to casual neighbourhood or "vicinal" contact, 23 per cent. to infection at school, and 51 per cent. were secondary cases in the home due to familial contact. The excessively high risk of infection within the home is shown by the fact that up to age 15 approximately 90 per cent. of the susceptibles—i.e., without a history of previous attack—succumbed on exposure to a case in the family. Secondary attack rates on susceptibles in attacked schools were considerably lower, being estimated at 41 per cent. at ages under 10 years and 15 per cent. at 10 years and over. On the other hand, Dr. WHEELER emphasises the fact that if the word *spread* be defined as distribution among households instead of among individuals in the community there is no doubt that school attendance in this rural area was responsible for more cases than any other influence. The disease did not become widely distributed except through school attendance.

Can any measures be applied to restrict infection in an attacked school and thus in the homes of the neighbourhood, where the pre-school child is particularly in need of protection? Dr. WHEELER puts forward a number of suggestions. A communicable disease history of each pupil should, he maintains, be recorded on entrance to school and brought frequently up to date. This would identify the susceptibles. Three possible experimental procedures might then be applied: (a) The dismissal from school for a few days of any susceptible child with a cough of the dry consecutive variety. The loss of school time—apart from other factors—through false alarms might be more than saved by a reduced incidence of whooping-cough. (b) The use of gauze masks by all susceptibles showing suspicious symptoms. (c) Inoculation, which in such an area as this might well be tried as a controlled experiment. But even effective preventive action could at the best, according to Dr. WHEELER's calculations, reduce the incidence by only about one-half. Had a perfect system of prophylaxis been applied in the schools of this area at the time of the survey it would have eliminated, he computes, 66 cases which were secondary to primary cases in the various attacked schools, and 75 cases secondary to the former in the households where they lived, or 133 of the total 280 cases recorded, for even if the attack was only postponed, some at least of

<sup>3</sup> Weygandt, W.: *Psychiatr.-Neur. Woch.*, 1935, xxxvii., 619; Lichter, Ch., et Lichter, N.: *Vol. Jubilaire en l'honneur de Parhon*, 1934, p. 281.

<sup>4</sup> See, for example, *Amer. Jour. Pub. Health*, 1936, xxvi., 8.

<sup>5</sup> *M.M.F. Quarterly*, October, 1935, p. 366; January and April, 1936, pp. 81 and 180.

the children's lives would be saved by this delay. This proportion is not to be despised. Certainly in such an area the school appears to be the most hopeful point of attack.

### BENEVOLENT HOSTS

ON Wednesday of last week many of the officers and subscribers of the Royal Medical Benevolent Fund were entertained by the Royal Society of Medicine. Sir Thomas Barlow, president of the Fund, assisted Dr. Robert Hutchison, president of the Society, in bidding the guests welcome, and not far off was Sir D'Arcy Power, chairman of the management committee of the Fund. They would be grudging guests who required more than the pleasure of the company of such hosts, but the reception was followed by a variety of entertainment which Sir Thomas Barlow described as unique in his experience. The sleight of hand was marvellous, and the transference of treasure may have been emblematic of the intention to charm handsome gifts from willing subscribers. Had this not been the object of the reception many of the guests might have felt uneasy at the

contrast between the comforts showered on them and the discomforts set out movingly in Sir Thomas Barlow's centenary record and appeal. "Many doctors who are zealous, unremitting and effective in the serious illnesses of poor people are very hardworked indeed. The expectancy of life of a busy practitioner amongst the poor is not a long one." The sentences are taken from this appeal which, with Sir Thomas's own starting contribution of £1000, has reached nearly £3000, but is still far remote from the £20,000 which it is hoped to raise from new subscribers, apart from the special donations wanted for urgent and distressing cases and especially for the training of orphans to be self-supporting. Dr. Hutchison, although as is proper in a host he made no appeal, did make it clear enough that the success of the centenary year would gladden Sir Thomas Barlow's heart and set a seal on his work. We commend his words to any whose names are not yet to be found in the list of subscribers for the year 1935, and remind those whose names are there to add the little more which would make all the difference to some individual case of hardship.

## ANNOTATIONS

### VIRUS-TUMOURS AND TAR

FACTS now coming to light concerning virus-tumours and chemically induced tumours in mammals and birds must cause us to consider more and more closely whether the gap between two schools of thought in cancer research is not an entirely imaginary one. The first definite evidence that carcinogenic chemicals and viruses might act in concert in causing tumours came from McIntosh's report<sup>1</sup> that three tar-induced sarcomata in fowls had proved transmissible in series with cell-free filtrates, the agent in the filtrates behaving like a virus. More recently, Parsons at the Royal Cancer Hospital has described a sarcoma accompanied by leukaemia in a mouse treated with a soluble dibenzanthracene compound; this, it is reported,<sup>2</sup> has been successfully filtered on four occasions.

Now comes more startling news from Peyton Rous's laboratory.<sup>3</sup> Rabbits tarred on the ear began to show hyperplasia and small warts in 1½-3 months. Ordinarily such warts regress if the tarring is stopped at this stage; to obtain cancers it is necessary to tar for a year or more and even then they will appear in only a minority of animals. Rous and Kidd took rabbits tarred for a short time and inoculated them intravenously with large amounts of filtrates of the Shope rabbit papilloma. After a fortnight, the normal incubation period of this virus, the growths in many rabbits underwent an extraordinary change, becoming discoid and infiltrative within a few days. Biopsies showed that numerous discrete, highly anaplastic carcinomas had appeared. Some of these developed on the basis of pre-existing tar warts, but others where none had been visible. In one instance an anaplastic cancer appeared within 22 days after the virus inoculation. The changes were progressive and usually led to the death of the rabbits within a few weeks. Rous and Kidd have failed to find any

previous record of fulminant carcinosis such as this, and nothing of the sort appeared in their numerous control animals.

It will be recalled that the Shope papilloma virus inoculated on to the skin of domestic rabbits produces warts which at first appear quite benign, but after some months may develop into metastasising epitheliomata.<sup>4</sup> The precancerous (papillomatous) period can be shortened in various ways, as by bacterial infection or injection of Scharlach R., but in the latest experiments it appears to have been abolished altogether. Few would have prophesied that the papilloma virus, which induces cancers only after several months, would, when combined with an agent having an even longer period of induction, let loose a fulminant carcinoma in a few weeks. The result is especially suggestive, since previous attempts to obtain tumours quickly by combining several chemical carcinogenic agents have failed. An attempt to interpret these findings would be premature, but it is clear that a field of research of enormous interest has been opened up.

### CORAMINE AS AN ANTIDOTE TO THE BARBITURATES

THE great efficacy of Coramine as a stimulant to respiration has been recognised for some years. It was recently discussed at a meeting of the section of therapeutics and pharmacology of the Royal Society of Medicine,<sup>5</sup> where, though a little doubt was thrown on its value, the majority expressed their faith in the drug, and some described excellent results obtained from its use in all conditions associated with shock and depressed circulatory and respiratory states. Anaesthetists have often used injections of the drug to improve the breathing when it has shown signs of failing or has actually stopped. This action of coramine has been taken advantage of especially in connexion with depression of respiration arising after

<sup>1</sup> McIntosh, J.: Brit. Jour. Exp. Path., 1933, xiv., 422.

<sup>5</sup> THE LANCET, 1935, II., 1122.

the use of basal narcotics. An interesting series of clinical experiments is described<sup>6</sup> by Dr. P. G. Schube, which shows the remarkable power possessed by coramine of counteracting the effects of barbiturates. It is not merely the increased depth and frequency of respiration and improved circulation which follow the administration of coramine, but also the extraordinary cutting-short of the unconsciousness that had been induced by large amounts of barbiturate. The opportunity to test these results arose in the psychiatric clinic of the Boston State Hospital, the patients being all "mentally ill but physically normal." Tests were carried out on 84 patients, the controls receiving barbiturate but no coramine. In the other patients the coramine was given intravenously 5 c.cm. first, and if consciousness had not returned at the end of ten minutes another 5 c.cm. every ten minutes until the patient was conscious. It is stated that in each instance when coramine was injected "the state of unconsciousness was abolished, some persons having to receive more coramine than others to achieve this result." In the controls, unconsciousness lasted for hours longer than in those that had had coramine, in whom it was only a matter of minutes. It is notable that in all these patients the pulse-rate and volume were unaltered although respirations were increased both in rate and in depth. Some of the patients vomited after 10 c.cm. of coramine had been injected. There were no after-effects, and the author concludes that "coramine is an excellent drug to counteract effects produced by barbiturates."

#### MEGALOCYTTIC ANÆMIA IN BRITISH GUIANA

In 1904 Kennard described<sup>7</sup> an acute anæmia of a pernicious type affecting East Indians in British Guiana; it was seen in both sexes but was definitely more prevalent in pregnant women. This work received little notice for thirty years, but its accuracy has now been confirmed by Giglioli<sup>8</sup> in an important and detailed study of megalocytic anæmia in British Guiana. In a period of twenty months Giglioli found no less than 51 cases of megalocytic anæmia in an aggregate population of 4127 persons. It was commoner in females, the ratio among adults being 5.5 females to 1 male. The age-incidence varied from 11 to 44 years, the majority of the patients being between 17 and 30 years old. Among the women the most characteristic feature in the history was the occurrence of previous attacks in association with pregnancy. The symptomatology was similar to that of Addisonian pernicious anæmia except that nervous complications were not seen. Glossitis and stomatitis were frequent. Splenomegaly was considerably greater than that found in other forms of megalocytic anæmia or in local cases of malaria. The anæmia was usually severe, the red cells being as a rule below 2,500,000 per c.mm. The true colour-index was difficult to assess owing to the method of hæmoglobin estimation used, but Giglioli considers it was high in most of the cases. Red cell size as measured by halometer technique was increased. The indirect van den Bergh reaction was always higher than normal. The anæmia responded in a classical way to treatment either with liver extract or with Marmite. Pregnant women if appropriately treated rapidly recovered and went to term normally, delivering strong and healthy infants. All the males, though

they showed a greater tendency to relapse, also made good recoveries. Before its recognition and treatment this grave anæmia is thought to have been the main cause of maternal and neonatal mortality and stillbirth in the district under investigation, since over a third of the infant mortality during the last twenty years has been registered as due to prematurity and congenital debility—i.e., to maternal disease. Apart from its obvious social and economic importance, however, this study raises interesting problems for the hæmatologist. Discussing the ætiology of the anæmia and its relationship to the tropical megalocytic anæmia of India, Giglioli concludes that ankylostomiasis is not an ætiological factor. The local distribution does, however, seem to be related to that of malaria, and he believes therefore that malaria plays a part in the development of the anæmia. It is possible that the associated malaria may explain the constant finding of an indirect van den Bergh reaction above normal which appears to be a striking point of differentiation from the anæmia of a similar type in India. No data concerning the diet or gastric secretion are yet available. The fact that the anæmia responds so well to marmite suggests that a dietary deficiency, associated with the additional demands of pregnancy, has a good deal to do with its development.

#### VOLKMANN'S ISCHÆMIC CONTRACTURE

THE grave changes in muscle from impairment of blood-supply following on a fractured bone were first described by Rich. v. Volkmann (1830-89). Here this ischæmic contracture is most often seen as a complication of supracondylar fracture of the humerus in children. In considering its cause and treatment Meyerding<sup>1</sup> endeavours to define the responsibilities of the surgeon. Tight splinting of swollen elbows cannot be too severely criticised, and the danger of very acute flexion is well known, but it is not so generally recognised, he says, that it is possible for ischæmic paralysis to come on where no treatment at all has been given. The medico-legal importance of this is obvious: in fairness it is the first point that should be laid before a jury trying such a case in a court of law. The surgeon is wise who mentions the chance of ischæmic contracture before attending to any injury to the elbow-joint, especially if treatment has been delayed. Otherwise there is more than a possibility that all complications will be directly attributed to his treatment and to that alone. A few hours of impaired circulation is, after all, sufficient for damage of muscle. Restoration of the circulation in the limb should therefore be at least as anxious a care of the surgeon as the reduction of the fracture. Meyerding mentions in particular the repeated observation of the radial pulse and of the colour of the hand in the period following reduction. Severe pain is a danger signal; parents should be told of this, and also of the value of testing the active movements of fingers as evidence of good circulation in the hand. It is not always appreciated that even in cases treated early the effusion—and therefore the danger to the circulation of the limb—may develop after reduction. Meyerding found that there was malunion in 40 per cent. of cases of ischæmic contracture. He believes that often in the attempts to relieve pressure the bone ends again become displaced. He also suggests that patients with very swollen, cyanotic arms would be

<sup>6</sup> New Eng. Jour. Med., May 7th, 1936, p. 925.

<sup>7</sup> Kennard, C. P. (quoted by Giglioli): Brit. Guiana Med. Ann., 1904.

<sup>8</sup> Giglioli, G.: Report of the Surgeon-General of British Guiana, 1934, Appendix II. (B).

<sup>1</sup> Meyerding, H. W.: Jour. Amer. Med. Assoc., April 4th, 1936, p. 1139.

much more suitably treated in bed with the arm abducted than walking about with the arm dependent. Elevation of the elbow on pillows or the use of an aeroplane splint are both useful measures.

If the circulation is already impaired when the child first comes under observation, Meyerding advises treating the fracture as of secondary importance and leaving reduction until the pressure has been relieved. There is one criticism of this advice: the pressure may be largely a direct result of stretching the soft tissues over the sharp lower end of the humerus, and accurate reduction will relieve it. In a case of this nature the dangers to the patient and to the reputation of the surgeon are great, and consultation is often wise, because whether the decision is to watch the case (first removing all splints and bandages), to manipulate, or to remove clot and relieve pressure by open operation, there is a very good chance that the surgeon will bear the blame for any subsequent disability. Meyerding advises watching for about an hour, having removed all external pressure, with the elbow extended to more than a right angle and elevated. If the radial pulse is not restored and the swelling increases, he operates, incising freely over the hæmatoma and through the deep fascia. The bicipital fascia may be divided by an incision medial to the biceps tendon, and through this incision the artery is inspected to detect continued bleeding and the nerves are examined for damage. A Kirschner wire passed through the lower fragment he finds useful as an aid to reduction of the fracture.

In the fully developed deformity, Meyerding has obtained the best results by the gradual extension methods described by the late Sir Robert Jones. Wooden tongue depressors are used to splint the individual fingers, the length of the splints being increased as it becomes possible to extend the more proximal joints. Eventually the splints pass from the fingers up the back of the forearm. Active use of the joints is encouraged throughout. Open operation on the flexor tendons, with partial incision and stretching, has given some good results in bad cases, but in the presence of much degeneration of muscles and tendons shortening of the bones is advocated. Meyerding's paper is based on observations and records of 69 cases. He concludes that prevention is possible in many cases if the injury comes under treatment early, but that once the circulation is impaired to any extent, it may be impossible entirely to avert the danger, while in the presence of definite ischæmic contracture it is a mistake to expect very much from surgery.

#### A BINAURAL HEARING AID

For those deaf people who will consent to carry with them a box containing the apparatus, and are sufficiently deaf to need a powerful instrument, the valve-amplifier type of electric hearing aid is the most efficient. This apparatus reproduces sounds with great fidelity and over a wide range of tones, to which the smaller "portable" electric aids cannot attain, thus making speech far more intelligible. But all monaural aids are necessarily non-directional, and are accompanied by some reverberation which tends to confuse the hearing. These defects are not abolished merely by the use of two earphones, but it has been found by experiment that they can be surmounted by providing two entirely separate microphone-amplifier-earphone channels for the two ears. Amplivox Ltd., of 106, George-street, Portman-square, London, W.1, have produced such an instrument, in which the microphones, of

piezo-electric type, are placed at an angle of 90 degrees to each other and about 9 inches apart. The case contains six midget valves with H.T. and L.T. batteries and is wonderfully compact, for it measures only  $12 \times 3\frac{1}{2} \times 4\frac{1}{2}$  inches. The 2-volt accumulator gives 20 hours' service on a charge, and the dry H.T. battery has a life of about two months. The price of the instrument is 30 guineas. The directional effect is very noticeable at ordinary distances in a room; there is less confusion from reverberation, and a general improvement in naturalness as compared with the monaural instruments. It will be particularly useful in office and board-room to those severely deaf people who require the most natural reproduction of sound at present attainable, but it is a transportable rather than, in the ordinary sense of the word, a portable machine.

#### THE LISTER INSTITUTE

THE question whether an institute devoted to medical research should or should not be closely associated with a hospital is one which has long been and will long continue to be debated inconclusively whenever two or three doctors are gathered together. The main arguments used on either side are easy to construct. One contends that unless the staff are stimulated by contact with clinical material and by the requisitions made to them daily by physicians and surgeons their outlook will become academic and they may spend their lives studying problems which have no practical bearing; on the other side it is held that the work of the staff of a pathological institute attached to a hospital tends to become ancillary to that of the clinicians, whose demands on their time and attention are irresistible when made in the name of sick people. Such discussions seldom remain abstract; they usually degenerate into an animated game of attack and defence of institutes alleged to have become permanently unfruitful; of others whose recovery from lethargy dated from the clinical application of a discovery incidental to an unproductive line of work; of routine workers whose contribution to medical knowledge could only have been made as the outcome of hospital experience; and of occasions where the obstinate conservatism of the general practitioner was eventually justified by evidence rehabilitating a discredited remedy. In the end there is usually an admission that however fully the observational method is exploited in medical research there is still and will always be scope, even from the utilitarian point of view, for the institute where workers are free to pursue experimental investigations without direct relevance to patients, since none can know when any scrap of knowledge fitted to another will bear fruit. These reflections arise out of a study of this year's report of the governing body of the Lister Institute. Here is an organisation whose recent activities, to say nothing of the past, have had a profound effect on modern medicine; for example, the investigations into the morphology of viruses by the present director, Prof. J. C. G. Ledingham; the nutrition studies of Sir Charles Martin, Harriette Chick, E. M. Hume, and S. S. Zilva; the pioneer work on antigenic structure of bacteria by J. A. Arkwright and A. Felix; and the studies of phosphate metabolism and the calcification of animal tissues by R. Robison and his colleagues. There can be little doubt that at any rate in a town as large as London there is room for an institute in which the staff are quite unhampered by routine duties. When the need arises for coöperation with clinical colleagues,

as in the development of the work on the aetiology of rheumatism noted on p. 1435, it is easily secured. Meanwhile the Lister Institute and its younger sister, the National Institute for Medical Research, Hampstead, have a special function in enlisting the help of those trained in more exact sciences in the solution of medical problems.

### OCCUPATIONAL SELECTION

THE latest report<sup>1</sup> of the Industrial Health Research Board should be read in conjunction with the article by Squadron-Leader R. H. Stanbridge which appears on p. 1426 of our present issue. Both bear witness to the value of psychological tests in occupational selection. Squadron-Leader Stanbridge's work will no doubt be more easily comprehended by the general reader than that of the Industrial Health Research Board's investigators, since it is far less technical and concerns a more limited problem. But a comparison between them is of value, because they have employed similar tests; indeed, the same linguistic intelligence test—the National Institute of Industrial Psychology's group test 33—was used in both researches. In each, the value of this particular intelligence test was clearly confirmed, and in each the value of tests of mechanical aptitude (derived, it would seem, from tests devised by Dr. J. W. Cox, research fellow of the National Institute) was upheld. Neither research adds very greatly to information already available about mechanical aptitude, but the Board's investigators find themselves able to lend support to Dr. Cox's thesis that a specific mechanical aptitude exists independently of general intelligence, although functioning in conjunction with it. It is perhaps a little unfortunate that Mr. Farmer and Mr. Chambers chose to follow up their statement of this conclusion with the obscure generalisation that this mechanical factor "is involved in tests depending on manual or reasoned reactions to perceptual imagery."

The male workers who made up the fourteen groups tested by the Board's investigators varied in age between 14 and 38½, and there were 2731 of them altogether. Some were apprenticed to skilled types of engineering; some were engaged in simple upholstery work involving much repetition; some were employed in repetitive light casting; some were being taught to drive and repair heavy lorries and tanks; some were training for various manual trades; and some were being given instruction in visual and auditory signalling. From their study of this material Mr. Farmer and Mr. Chambers conclude: (1) Intelligence tests could with advantage be adopted in the selection of candidates for highly skilled work; or for work which may appear highly skilled to those likely to be employed, on account of their relatively low level of intelligence. (2) Intelligence tests appear to have no selective value where the occupation is of a routine type of a simple kind. (3) The argument that performance tests of intelligence are more appropriate than linguistic intelligence tests for vocational selection in low-grade groups is not supported by the data available. (4) The National Institute's form relations test appears to have considerable value as an aid in selecting candidates for occupations which involve visual perception of form in a static field, but it does not seem to be satisfactory for occupations which involve visual perception in a moving field. (5) The failure of certain tests which were chosen because they appeared to involve pro-

cesses involved in certain of the occupations dealt with serves as a warning to constructors and users of tests of this "analogous" type. Before selection tests are used for practical purposes their validity should be clearly established. (6) The evidence obtained from following the after-careers of certain of the skilled engineering groups is opposed to the frequently made suggestion that psychological tests have prognostic value only during the learning process. On the contrary, it shows that such tests correlate more closely with proficiency when maturity has been reached than with proficiency at the end of the learning period.

Squadron-Leader Stanbridge has provided us with an interesting set of data concerning approximately 1100 aircraft apprentices, between the ages of 15 and 17. His findings lead him to suggest with considerable confidence that the tests he found most valuable—the intelligence and mechanical tests—should be used as supplements to the ordinary scholastic examination which is given to applicants for Royal Air Force aircraft apprenticeships. His results do not encourage him to place any great trust in the "perseveration" test he employed. This conclusion seems to be in line with the general scepticism with which such bodies as the National Institute now tend to regard so-called perseveration tests. Vocational psychologists will read both the report and the article with lively appreciation. Some of them will perhaps feel a little envious of the opportunities in the Royal Air Force for carrying out research work of this kind.

### THE EXOPHTHALMOS OF GRAVES'S DISEASE

THERE is something peculiarly fascinating about the unsolved problem of the mechanism of exophthalmos in exophthalmic goitre. Dr. Russell Brain, who has been interested in it for years, devotes the greater part of a recent address, on Some Problems of Thyrotoxicosis,<sup>1</sup> to facts and speculations that bear on it. He regards a rise of pressure in the conical space behind the eyeball, bounded by the rectus muscles, as the probable immediate cause of the protrusion, and he attributes this pressure rise to contraction of strands of smooth muscle acting directly on the eyeball, and also indirectly by constricting the retro-ocular veins and causing their engorgement. He then looks for a stimulus which would make the orbital smooth muscle contract. It is not the sympathetic nerve-supply, for division of this is without effect on exophthalmos, nor is it the thyroid over-activity, for the most that thyroxine can be shown to do is to sensitise the smooth muscle or the nerve-endings to the action of certain drugs. But a number of workers have recently shown that the thyrotropic hormone of the pituitary will induce exophthalmos as well as hyperthyroidism in animals, and indeed will induce exophthalmos in thyroidectomised animals. "It is a tempting hypothesis," Dr. Brain writes, "that this . . . may be concerned in the pathogenesis of exophthalmic goitre," and most of us will be tempted with him. But in yielding, we must not dismiss the sympathetic too summarily, for the hormone produces its effect in animals only if the sympathetic is intact, and therefore presumably should act in man in some way through the sympathetic. Failure of cervical ganglionectomy to abolish established exophthalmos, however, does not necessarily upset this theory, for the common persistence of exophthalmos after the subsidence of hyperthyroidism has long suggested that the physiological

<sup>1</sup> The Prognostic Value of Some Psychological Tests. By E. Farmer and E. G. Chambers. Report No. 74. Pp. 41. 9d.

<sup>1</sup> London Hosp. Gaz., April-May, 1936, Clin. Suppl.

changes which evoke it are succeeded by irreversible anatomical changes—such as fat accumulation—which maintain it.

If exophthalmos is difficult to explain, external ophthalmoplegia associated with exophthalmic goitre is still more mysterious. It is uncommon. Dr. Brain attributes the first record of it to Dr. Francis Warner of the London Hospital in 1882, and he himself has collected 22 cases which he presented to last year's International Neurological Congress. Because he finds the ophthalmoplegic complication rather often in male patients and almost always in middle life, and because the accompanying hyperthyroidism is often mild and occasionally extinct, he regards the whole syndrome as distinct both from "primary" exophthalmic goitre and from so-called "toxic adenoma" of the thyroid. This is perhaps straining the argument rather far, but, since the ophthalmoplegia when it does occur is closely parallel to the exophthalmos both in its degree and in its incidence in one or both eyes, it may readily be conceded that both ophthalmoplegia and exophthalmos demand a causal explanation other than hyperthyroidism. The ophthalmoplegia need not be due to a central lesion; it may be a local lesion of the muscles or their nerves, produced like the exophthalmos by pressure changes in the vessels and fluid contents of the orbit. This brings us back to the pituitary hypothesis, and the animal experiments suggesting that thyrotropic hormone can act through the sympathetic on the orbital contents—clearly the most inviting point of attack for those who would investigate further the problem of the pathogenesis of exophthalmic goitre.

#### IONISATION FOR HAY-FEVER

ZINC ionisation as a method of relieving hay-fever came into prominence last Saturday when the newspapers announced that it has proved successful in 99 per cent. of cases treated at St. George's Hospital. The procedure is to pack the nasal cavities with cotton-wool or gauze soaked in zinc sulphate solution, insert electrodes into the nose, and then pass an electric current, through the solution, to an indifferent electrode applied to the forearm. The result aimed at is a shrunken mucous membrane which will be insensitive to pollen and other stimulants of rhinorrhœa. The steps taken to achieve this object are described in greater detail by Dr. Clive Shields, of the physiotherapy department at St. George's, in the May number of the *Practitioner*. Broadly speaking he follows the technique employed by Philip Franklin for many years,<sup>1</sup> but he packs the nose with  $\frac{1}{2}$ -inch ribbon gauze instead of cotton-wool and unless the nose is supersensitive uses 2 per cent. zinc sulphate solution rather than 1 per cent. The nose is previously sprayed with 2 per cent. cocaine, "as otherwise the treatment is extremely uncomfortable for the patient," and since there is usually much sneezing and rhinorrhœa 2-12 hours later a sedative is often advisable. Dr. Shields finds that most patients with seasonal hay-fever are free from attacks for about a year after three or four treatments. "Two prophylactic treatments should be given yearly for the next two years and may then be safely omitted. Some cases relapse, but it seems probable from cases observed since 1931 that the attacks respond to one or two further treatments." Mr. Franklin, with his longer experience, is not quite so confident, as will be seen from his letter on p. 1442. Though the use of ionisation for this purpose finds many advocates in the United States and is clearly worth a trial when a patient is seriously

disabled by hay-fever, it is evidently not appropriate for slight cases that can be relieved by simpler means. Dr. Shields thinks it useless to attempt the treatment in the presence of dental sepsis, infection of the paranasal sinuses, and obstruction to the nasal passages from organic causes such as deflected septum, enlarged turbinates, and polypi. But even if the patient is lucky enough to start with a clean sheet in these respects the final issue cannot, we understand, be foretold with complete confidence. A result which is certainly to be avoided is the inadvertent destruction of olfactory function, and with this in mind the patient should sit up, and not lie down, while the ionisation is in progress.

#### TISSUE CULTURE IN STUDY OF THE VITAMINS

A SOMEWHAT new approach to the study of vitamin deficiency was opened when Sir Robert McCarrison and G. Sankaran<sup>1</sup> at the nutrition research laboratories of the Indian Research Fund Association at Coonoor, noticed that cultures of embryonic tissues grew much better in plasma from normal animals than in plasma from fowls with beri-beri, suffering from deficiency of vitamin B<sub>1</sub>. The work has now been carried further by Sankaran in conjunction with McCarrison's successor at the laboratory, Dr. W. R. Aykroyd.<sup>2</sup> It is pointed out that the dietary of the beri-beri pigeons was deficient in vitamin A as well as in vitamin B<sub>1</sub>, and this time the growth of embryonic fowl spinal cord and rat cerebral tissue in plasma from fowls and rats suffering from vitamin-A deficiency has been investigated. Three types of plasma were examined: plasma from normally fed animals; plasma from animals on a basal diet deficient in vitamin A; and plasma from animals receiving the basal diet supplemented by cod-liver oil. Examination of the rate of growth of the cultures left no doubt that there was a real difference between the different types of serum. To eliminate all subjective influences, observers judged the cultures in ignorance of their nature. The cultures in deficient plasma always gave poor growth, while those in normal plasma gave good or occasionally medium growth. The plasma from animals on the deficient diet, supplemented, gave an intermediate result. This last observation is in accordance with general experience that the most perfect synthetic diet, "completely" supplemented, usually gives a biological result inferior to that given by a complete normal diet. The cause of the failure of the tissue implants in plasma from A-deficient animals was not established. It may well be that there was an actual deficiency of vitamin A in the serum. The possible relationship of these observations to E. Mellanby's suggestion<sup>3</sup> that the nerve lesions are the primary ones in vitamin-A deficiency, and the epithelial ones secondary, is of considerable interest.

MEDICAL TOUR IN GERMANY.—In connexion with the Olympic games in Berlin a medical study tour of the universities and spas of Germany has been arranged. The party will leave Berlin on August 17th, arriving in Hamburg on the 30th, and visits will be paid to Dresden, Nuremberg, Rothenburg, Munich, Tübingen, Baden-Baden, Heidelberg, Bad Nauheim, and Wiesbaden. The party will sail down the Rhine from Biebrich to Coblenz, and then make its way by Cologne, Leverkusen, and Bremen to Hamburg. Further information may be had from the Deutsche Gesellschaft für ärztliche Studienreisen, Berlin, N.W.7, Robert Koch-Platz 7.

## PROGNOSIS

*A Series of Signed Articles contributed by invitation*

### CIV.—PROGNOSIS OF HAND INFECTIONS

*(Concluded from p. 1370)*

#### Paronychia

This is a special variety of whitlow in which pus appears at the base of the nail. It is important to realise that the pus is primarily situated under the proximal part of the nail. For this reason a curved incision through the skin is useless, as it never reaches the site of the pus. The common operation of removal of the nail is likewise unsatisfactory, as there remains a flap of skin at the proximal end under which suppuration still continues, and healing is uncommon under six to eight weeks. A flap of skin must be turned back so as to expose the base of the nail, which is then removed with scissors, without sacrificing the exposed portion. The flap is held back with a strip of vaselined gauze (which does not obstruct drainage) until suppuration has ceased. Healing can be expected in ten to fourteen days.

#### Lymphangitis

Lymphangitis is readily diagnosed by the presence of diffuse oedematous swelling, with little or no local suppuration, but with red lines spreading up the arm, and early pain in and swelling of the lymph glands. A state of septicæmia is usually present and dominates the picture, and it is not uncommon for the patient to complain of malaise and fever without remembering a trivial injury to a finger. The illness may take one of the following courses:

1. The patient may pass into a state of profound septicæmia and die within 24 to 48 hours.
2. After a stormy septicæmic illness, with suppuration in the lymph glands and distant metastases, gradual recovery may ensue.
3. After a septicæmic stage and defervescence, local suppuration in the hand may require treatment.
4. After defervescence the condition may clear up entirely without suppuration.

Incision is definitely contra-indicated in the presence of lymphangitis, except late in the disease when local suppuration has established itself. The patient must be treated by absolute rest in bed on a splint, with massive hot compresses to the whole arm, and copious fluids by the mouth. The value of serum is problematical; nor has intravenous chemotherapy proved of great value. In fact the prognosis seems to depend much more upon the virulence of the particular organism in each case. The illness may last from a few days to many months, and while the hand usually recovers completely, permanent damage in distant parts may seriously handicap the patient.

#### Dorsal Infections.—Carbuncles and Boils

Dorsal infections are less common than infections in other areas of the hand, and are usually due to infected wounds in the neighbourhood of the knuckles. Particular attention should be drawn to the chronic nature of infections following injuries inflicted by teeth (as in street fighting) and those arising from the bites of dogs or cats. A chronic inflammation may last for weeks, even in the absence of gross suppuration. The ease with which the joints become involved in dorsal injuries is also noteworthy, as only a thin extensor expansion intervenes between the skin and the joint cavity. Suppuration in a

joint almost always leads to ankylosis, the inconvenience of which has already been stressed.

*Boils and carbuncles* may occur on the dorsum of the hand and fingers, as in any hairy parts. Resolution is the rule, when treated with cupping and ultra-violet light. Incision should rarely be necessary, and by avoiding it scarring and deformity are reduced to a minimum.

#### Effect of Infection on the Hand as a Whole

One of the most sinister effects of hand infections is the development of an insidious stiffness of the whole hand when only one part has been diseased. It is sometimes due to the patient's fear of movement, sometimes to prolonged and misapplied splinting, but it may occur in spite of every effort directed to maintain mobility. Persistent œdema is a potent cause. The stiffness may, moreover, take months to overcome, and in the more severe cases is a permanent disability.

It requires nice judgment to determine, in these as in all infections, the correct balance between rest and activity. Absolute rest is essential in the early stages of treatment, but as soon as the local condition is under proper control active and passive movements are to be encouraged. As suppuration diminishes hydrotherapy, radiation, massage, electrotherapy, and occupational movements are of supreme value in restoring function. The preservation of the "position of function" in the early stages assists materially in reducing the time required for this restoration.

#### Summary and Conclusions

An attempt has been made to indicate the course of each variety of hand infection, the prognosis under proper treatment, and the complications likely to ensue with improper treatment. The prognosis of paronychia, subcuticular and uncomplicated subcutaneous whitlows should be good, with full restoration of function. The prognosis of tendon sheath infections is usually bad, while bone involvement complicating any infection leads to permanent deformity and disability.

The ultimate prognosis must be considered not only from the point of view of subsidence of infection, but from the point of view of return to work and final function. The average period of incapacity from work was 6-8 weeks in a large series of cases, though this figure is somewhat inflated by those cases that have an abnormally long period of incapacity (1-2 years). Three to four weeks is a fair average. This does not take into account cases of permanent disability, nor the fact that the loss of a finger, or the loss of function of a finger frequently necessitates change of occupation, which is in itself a handicap especially to the working man. That the prognosis in general is capable of improvement cannot be doubted, for prophylaxis, early hospitalisation, carefully studied treatment and after-care should materially reduce the dangers of this common condition.

NILS ECKHOFF, M.S., F.R.C.S.,  
Assistant Surgeon, Guy's Hospital.

POSTER COMPETITION.—The Great Ormond-street Hospital announces a competition for a poster design to raise money for the reconstruction fund of the institution. Prizes will be £50, £20, and £5.

## SPECIAL ARTICLES

## THE OCCUPATIONAL SELECTION OF AIRCRAFT APPRENTICES OF THE ROYAL AIR FORCE\*

By R. H. STANBRIDGE, M.R.C.S. Eng., D.P.M.  
SQUADRON-LEADER, ROYAL AIR FORCE

THIS paper deals with the use of psychological tests in the selection of personnel. The object of the investigation, which began in 1932, was to find if it was possible to predetermine, more accurately than hitherto, whether a candidate is suitable for acceptance as an aircraft apprentice; and, if so, the nature of employment most appropriate to his abilities and character. Also to obtain a greater knowledge of him—as an individual—than can be got from the results of a written examination.

An aircraft apprentice is a boy who enters the Service between the ages of 15 and 17, is allocated immediately one or other of the trades in which there are vacancies, and undergoes a course of training at a training centre. The allocation of his trade is made in accordance with his parents' choice or his expressed desire, but this is of course subject to many factors, such as Service requirements and his placing at the scholastic examination prior to entry. The course of training is very thorough, lasting three years, and takes into consideration the requirements not only of the Service, but also of his eventual return to civil life. It was a matter of experience that such factors as those mentioned (the requirements of the Service, and parents' choice of trade) were not of themselves certain to prevent the placing of square pegs in round holes, and this was an additional reason for our endeavour to find some form of supplementary examination which would give more information about capacities and incapacities.

The factors operating to produce misfits are many, amongst them being:—

- (1) Lack of prior knowledge of the requirements and nature of various trades, and of Service life generally.
- (2) The inability of the individual to adapt himself to the demands of the Service.
- (3) The fact that a low place in the entry examination may result in all vacancies in the desired trades being filled before the boy's turn comes.
- (4) The degree of national unemployment, tending to cause boys with no leanings towards the Service to join it.

The effects of unsuitable selection are obvious. They may be summed up as maladaptation to life, and they manifest themselves in such ways as slowness to learn, insubordinate or undisciplined behaviour, and symptoms and signs of worry like neuroses and abnormal conduct. The cost of training an aircraft apprentice is considerable, and it is important to ensure that the State gets the best, or at least a reasonably good, return for this expenditure. Apart from the immediate advantage to the State and to the Service we also have to consider the making of a good citizen who on return to civil life will be fitted to take a worthy place in his selected trade, and—more even than this—the avoidance of unnecessary unhappiness and possibly disaffection.

\* Read before the United Services section of the Royal Society of Medicine on March 9th.

### GENERAL DESCRIPTION OF THE TESTS EMPLOYED

The method chosen for testing occupational aptitude was based on the principle that a man's behaviour is an expression of his personality as a whole, and that personality is compounded of intellect, temperament, and character. It was thought that much of the objection to psychological examinations may arise from a tendency to draw too many conclusions from the results of an isolated test, and that consequently a combination of psychological tests with a medical examination might take us a step forward. It was therefore decided to collect data for each individual in respect of the following attributes: physique, temperament, character, intelligence, mechanical ability (the actual performance of certain mechanical tests), and mechanical aptitude (answers to written theoretical questions). Then from such data (which were obtained as soon as possible after he had joined the Service) assessments and final classifications were to be made under definite headings such as:—

- (1) Poor types (should not have been accepted)—i.e., those likely to be backward or difficult or temperamentally unsuited to Service life.
- (2) Those likely to do well, potential cadets, fit for promotion, &c.
- (3) For further observation physically.
- (4) Should have been given a different trade.

A report giving the names under these headings was then to be forwarded to the command headquarters for filing\* until the entry had completed the three years' course, when the passing-out categories could be correlated with the original forecasts. The methods employed in this examination will now be explained.

A special record card was prepared to record the data. These are conveniently divided into two divisions: (1) the individual examination, and (2) the collective examinations.

### THE INDIVIDUAL EXAMINATION

*Interview.*—Each boy is interviewed alone in a room designed to make him feel at ease. He is asked for information under the following headings: name; number; age; trade; birthplace; father's occupation; position in family (with notes as to step-relations, if any); previous occupation and/or school; reason for joining the Service; hobbies; games; early medical history as to signs of nervous or abnormal tendencies; general physical and mental background; position in entrance examination; choice of trade; whose choice, whether it was changed, and, if so, whether voluntarily or as a result of his position in the order of merit in the ordinary entrance examinations; if voluntarily, the reasons for the change.

*Physical Examination.*—Height, weight, chest expansion, dynamometer reading, condition of tonsils, heart, and lungs, 40 mm. test, assessment of psychological type, and measurements for the Wertheimer index.

The dynamometer consists of a scale with a handle attached and connected with a base upon which the boy stands, grasping the handle, to which he gives an upward pull from a slightly forward-inclined position. A reading is given which indicates the combined power of lumbar, abdominal, and shoulder muscles; a mean of three pulls is taken, and this

value, divided by the body-weight, gives an index figure. The height of the handle is adjusted for each boy so as to standardise the reading.

The 40 mm. test is the standard used in the Royal Air Force as an endurance test. A column of mercury has to be sustained in an open U tube at a level of 40 mm. for as long as possible, the pulse-rate being recorded in five-second periods before and throughout the test.

**Assessment of Psychological Type.**—As is well known, Kretschmer has attempted to correlate physique with character. His principle is that on the one hand the tall, thin, so-called "tubular" man tends to be an introvert and in mental illness to show a particular type of reaction known as schizophrenic (asthenic); whilst the shorter, thickly set more "rounded" type tends to have an extravert temperament and in mental illness to show the manic-depressive reaction type (pyknic). He places a third group midway between these two extremes (athletic). This classification has the disadvantage of depending on the examiner's personal opinion, and Wertheimer has given a more scientific method of measuring physique by which the leg length and then the transverse and sagittal diameters of the chest and the trunk length is measured. By a special formula using the leg lengths as the numerator and the others as the denominator the ratio between the cubic capacity of the trunk and the cubic capacity of the limbs and head and neck is given. The result is a number and the low numbers indicate those of the "rounded" type of physique, the high numbers those at the "tubular" end.

We appreciated that the relationship between physique and personality had not been sufficiently proved to give by itself a measure of temperament, and that there were many factors complicating the issue, but it was thought worth while to include data

considered that if one was asked which were the two abilities of outstanding importance in successful apprenticeship in the Halton workshops the answer would be "the ability to construct from a model and also to read from a plan." The test given is designed to pick out these two abilities. The boy is shown a model which has been

FIG. 2.—Cranwell wiring test. "With the wire and two pieces of metal, copy the model, getting the two inside points two inches apart."

sectioned and from this section has to build up the complete model with the parts supplied (Fig. 1). This has to be done in 1½ minutes and marks are given on the following performance scale:—

No combination ..	0	4 combinations ..	4
1 " " ..	1	Complete combination ..	5
2 combinations ..	2	Complete combination and	
3 " " ..	3	inside 1½ minutes ..	6

**TEST 2.**—This is termed the Cranwell test, and was designed by a similar process as a result of observing the essentials required in successful apprenticeship at Cranwell where instrument-making and wireless telegraphy are taught. This work calls particularly for the ability of fine finger manipulation and for extreme accuracy, and the test consists in copying a model provided by wiring together two pieces of metal the points of which have to be a certain distance apart (Fig. 2). This has to be done in 3 minutes and is marked on the following set scale for wiring, accuracy, and effectiveness.

ACTUAL WIRING			
On one piece but bad ..	..	..	0
" " good ..	..	..	1
On both but bad (not tight) ..	..	..	2
" (tight but not close wiring) ..	..	..	3
" (tight but fair wiring) ..	..	..	4
" good (tight, no gaps) ..	..	..	5
Good and inside 2 minutes ..	..	..	6

ACCURACY OF MEASUREMENT				
Outside 3/16 ..	..	0	Within 1/16 ..	3
Within 3/16 ..	..	1	Accurate ..	4
" 2/16 ..	..	2		

**TEST 3** is made with the McDougall-Schuster dotting apparatus, and consists in dotting, with a pencil, holes in an irregular pattern on a revolving disc. It was included as a sensori-motor reaction type test.

This completes the individual part of the examination.

**THE COLLECTIVE EXAMINATION**

In the collective examination any number may be examined at one time. Three tests are given.

1. **Intelligence Test.**—This is the Group 33 standard test, used for adults over the age of 15, which was devised by the National Institute of Psychology. In it there are five tests ranging from a simple test in which pairs of words have to be marked as having the same, opposite, or unknown meaning, to the last test which consists of a number of reasoning problems.

The following examples indicate the nature of the

FIG. 1.—The Halton chuck test. The instructions are: "The model is a section of what you have to put together. Do not touch the model, but build up a copy of it with the pieces provided. Do not wait to be told to start."

obtained from the adolescent boy under these headings, which might, taken with the examination as a whole, throw further light upon this subject.

**Mechanical Ability.**—Under this heading there are three special tests, two of which are for the measurement of mechanical ability and the third is a sensori-motor test.

**TEST 1.**—This is termed the Halton test, and it was devised at Halton as the result of observing the nature of the work required in the workshops where the trades of engine fitter and aeroplane rigger are taught. It was

test, but are generally simpler than those which confront the candidate.

I. *Opposites.* (Time allowed, 3 minutes.)—Fifty pairs of words are given and the candidate (by underlining) has to say whether they have similar, opposite, or unknown meanings. The simple examples are :—

Rich	Poor	SAME	OPPOSITE	UNKNOWN
Big	Large	SAME	OPPOSITE	UNKNOWN

II. *Analogies.* (3 minutes.)—Twenty-five sentences are to be completed by underlining the appropriate word in the next line. Thus :—

GOOD is to BAD as WHITE is to—CLEAN, BLACK, WICKED, RED.  
BAKER is to BREAD as TAILOR is to—Tailoress, Cake, Man, Clothes.

III. *Mixed sentences.* (3 minutes.)—There are thirty sentences in which the words are mixed up. The candidate must decide on their proper order and indicate whether the statement is true or false. Examples :—

a roses odour pleasant have TRUE FALSE UNKNOWN  
freezes water hot when TRUE FALSE UNKNOWN

IV. *Completing sentences.* (Twenty questions: 10 minutes.)—The task is to underline the word, phrase, or number that makes the best sense, wherever there are three printed one above the other. (The underlining in these examples is left to the reader.)

Monday and Tuesday are years of the week.  
January months  
Autumn days

The man fell off his bicycle and cured his arm.  
climbed of and broke changed

V. *Reasoning.* (10 minutes.)—Eighteen assorted problems.

This test is designed to measure general mental ability and is a scientific method of estimating inborn capacity. An intelligence test of this sort has the advantage that it cannot be crammed for; the conditions are exactly the same for all candidates; and it consists in different tests designed to bring out native intelligence. No writing is required. It is not suggested that it takes the place of a scholastic test of general knowledge, but rather that it provides a more accurate method of grading candidates from whom a selection is required for a particular purpose.

2. *Mechanical Aptitude Test.*—In this test there are thirteen mechanical problems, ranging from one which consists in arranging some toothed wheels, and connecting-rods and pins, to make a cog revolve in a given direction, to one which involves the estimation of where a given point on a lever will be when an eccentric, which is attached to a shaft connected with the lever, has been given half a turn. As in the intelligence test, no writing is necessary. Alternative answers are printed and it is only necessary to underline the correct one. This has the advantage of standardising these tests and eliminating differences due to speed of writing, &c.

3. *Perseveration Test.*—This was considered to be the most promising of the tests for the assessment of character. The scientific estimation of character is a very difficult problem; but it is certain that there are many variable factors, both conscious and unconscious, in the observer and in the observed which may adversely affect the accuracy of personal assessments and which tend to be affected by personal bias. It would appear that the road to greater fairness and consistency lies in the direction of some set form of test common to all candidates. The test used is based upon the principle of setting up a habit and then breaking it. This is done by giving a set piece of transcription which is to be written as quickly as possible for a definite period, and then repeated for three more periods of the same length of time but with certain variations introduced in

each of the last three periods. Thus every *e* has to be turned into an *a*, and vice versa; or a *q* has to be introduced after every *e*; or every letter in every word has to be doubled. This test is based upon work done by Pinard who claimed that it enables an empirical assessment of character to be made. He maintained, for example, that both extreme perseverators and non-perseverators tend to lack perseverance and self-control, and to be unreliable and difficult, whilst the moderate perseverator tends to be considerate, self-controlled, and reliable.

COLLATING THE DATA

This concludes my brief and general description of the actual tests used and the principles upon which they rest. The results are recorded on the front of the record card. This side of the card necessarily consists mainly of numbers, because one object of this scheme is to eliminate the personal factor of the examiner so far as is possible, and that the tests should be common to each candidate and marked by a number depending upon performance timed by a stop-watch, and judged by a set scale of marks.

The next step is to interpret these numbers in terms of poor, below average, average, above average, and exceptional, so that an assessment may be made

FIG. 3.—Marks obtained in mechanical aptitude and intelligence tests, showing curves approximating to normal frequency curves. For mechanical aptitude the mean is 25.3 marks and the average 19-30; for intelligence the mean is 106.3 and the average 95-124.

on the back of the card for easy reference. This is done by plotting out performance marks against the number of boys scoring each mark in each entry, and the result is, broadly speaking, a normal frequency curve, with equal falls above and below a general average (Fig. 3). The production of such a curve in the results of marking these tests is an indication of the soundness of the method adopted.

We are now, therefore, prepared to turn over our record card and consider the assessment of these results. The headings under which these are made are as follows :—

*Physical.*—Based upon the psychological type, physical index, 40 mm. test, and any special physical characteristics. It has been possible as a result of data obtained

to suggest a grading scheme which may assist in the selection of athletes and in the regulation of their training.

*Character.*—Based upon the early history and background, body type, temperament assessment, and perseverance test.

*Mechanical ability* = (Halton, Cranwell, and dotting tests). *Mechanical aptitude* = The thirteen mechanical problems in the paper test. *Intelligence* = The five tests in the paper. Under each of these headings the numbers already obtained are transposed into categories derived from the graphs (Fig. 3).

*Trade most suited for.*—Based mainly upon hobbies; reason for joining the Service and reason for wanting a particular trade; and performance in the special tests.

*Leadership qualities.*—Based upon a review of all the facts.

*Tendencies.*—(a) Physical. (b) Temperamental.

Such *general indications* as, for example, that further observations on medical grounds is needed, or that it is considered possible that the boy may break down and develop neurotic symptoms, are noted here.

After considering the whole of the above information the candidate is placed in one of the following categories, different colours for each category being painted at the foot of the card for easy reference:—

- (1) Those who should do well, and suited for promotion or for cadetships.
- (2) Those who are unlikely to do well, may be difficult or backward due either to inability to learn a trade, or temperamentally unsuited for Service life.
- (3) Those who should have had a different trade.
- (4) Those needing further observation on physical grounds.

This completes the forecast, and the rest of the card is left for the recording later of his actual progress in his squadron, schools, and workshops, together with any special performance on the playing fields, or any special activity. This last section of the card records the marks scored in examinations for practical and theoretical work in workshops, and in schools, and the final trade category awarded him in his final passing-out examination conducted in workshops by the Trade Test Board. Distinctions such as the special award of a prize, or recommendation for cadetship, are also noted.

#### RESULTS

So much for the general outline of the principles and methods of this investigation. What can be said of the result of it all?

Since September, 1932, a total of some 1100 examinations have been made, and two complete entries of apprentices—namely, those joining in September, 1932, and in January, 1933—have completed their three-year courses and have passed out as trained mechanics to appointments in squadrons, &c. The Medical Research Council has therefore been able to make a statistical analysis of the results in connexion with these two entries. I do not propose to go into this in detail, but it is possible to summarise the conclusions briefly.

The method was to take the three main groups of assessments given under the headings: (A) those noted to do well, including potential cadets; (B) those noted as being unlikely to do well, including those considered unsuitable for the Service; and (C) others; and to compare them with the three passing-out ranks of: (1) cadets and leading aircraftmen (L.A.C.'s); (2) A.C.1's; and (3) A.C.2's and cases discharged from the Service as being unsuitable. It was found that Class A (likely to do well) contained three times as many cadets and L.A.C.'s as would be expected by chance, and contained no A.C.2's or discharges. Also that Class B (unlikely to do well) contained no cadets or L.A.C.'s, but

over twice as many A.C.2's and discharges as would be expected by chance. Moreover, this general tendency was consistent in the two entries, and by averaging these and stating the facts numerically, it is deduced that every thousand boys selected by this method would contain at the end of their training 10 more cadets and L.A.C.'s, 12 more A.C.1's, and 22 fewer A.C.2's and failures than would be the case if the boys were selected in the usual manner. This indicates a raising of the standard throughout.

To state these results in a different manner the Medical Research Council say: "This final assessment has a significant relationship with passing-out which may be illustrated by the following facts. In the September, 1932, entry, 138 boys were trained, and of these 14 became cadets and L.A.C.'s. If these boys had been chosen by this assessment, only 123 boys would have been trained to yield the same number of cadets and L.A.C.'s. In other words, there would have been a saving of 10.9 per cent. in the number of boys trained. Similarly in the January, 1933, entry there would have been a saving of 9.1 per cent. in the number of boys trained. On the average therefore, as judged by these two entries, a saving of 10 per cent. could be effected in the number of boys to be trained in order to yield the same number of boys of the highest rank as are yielded by the usual method of selection.

"Of the tests themselves, intelligence, mechanical aptitude, and mechanical ability were found to be the most valuable, and these combined with the entrance examinations gave a closer relationship with trade proficiency as measured by the final trade test than did the entrance examination alone. These results are statistically significant and have been yielded consistently, so that by all the available evidence there is every reason for putting them into practice and supplementing the entrance examination by these tests. This combined method of selection should pick out a set of boys with an increased number of the higher ranks at the end of their training, and decreased number of failures and unsatisfactory apprentices."

These conclusions are reached as a result of the statistical analysis of the relationship between the assessments made from tests and the actual final performance of the two entries some three years later. The foregoing may be referred to as "positive" results, but some of the "negative" results are interesting. By negative results I mean those tests which have been found not to correlate significantly with the passing out result. Thomas Huxley said "the benefits of Science are derived more from the methods than the product thereof"; in any event these negative results certainly have to be considered.

No relationship was found between the 40 mm. test, nor the physical type classification, nor the dotting test, and the passing-out category. The relationship between the character assessments and passing-out showed that none of those assessed as being "unreliable and lacking in perseverance" became cadets or L.A.C.'s, whilst none of those assessed as being "practical" became A.C.2 or were discharged as inefficient. Whether this assessment is capable of being rendered more significant by some modification of the tests involved is uncertain. The perseverance test alone did not show any relationship with passing-out rank.

As regards the interrelationship between one test and another it was found that there was a significant relationship between the mechanical aptitude test and the intelligence, mechanical ability, and dotting tests. Also that there was a relationship

just significant between the physical type and the 40 mm. mercury test due to the facts that (a) none of the "rounded" type (pyknic) were "below average" in the 40 mm. test, and (b) more of the middle type (athletic) are "below average" than would be expected by chance. The tests which inter-correlated in this way were the intelligence, mechanical aptitude, mechanical ability, perseverance, dotting, and entrance examinations, and there was no significant interrelationship other than those noted above.

There are one or two further observations to make. One intention of this examination was to attempt to assist the executive branch in a practical manner in selection and training of personnel. It has been possible to do this whilst the examination was in progress and independently of any statistical proof as to results.

For example, the question of selection of cadets is a very important one both for the Command and for the Service generally. A certain number of names are submitted from each entry, by the Air Officer Commanding, to the Air Ministry as being suitable to proceed to the Royal Air Force Cadet College, Cranwell, to undergo training to become commissioned pilot officers. Six names have been submitted in this way from each of the two entries which have passed out, and which have already been referred to. Whilst these numbers are too small to be treated statistically as a separate class, it is of interest to show that in the case of the September, 1932, entry, five of the six selected were classed previously as having leadership qualities, and as being potential cadets (the sixth being given a practical assessment above the average). Of the six recommended of the January, 1933, entry, four previously were classed as being potential cadets, and as having leadership qualities, and one as likely to do well, and the sixth was given a good practical assessment.

A further example of the uses to which this examination has been put is that it has been found possible to assist the instructors and commanding officers in the backward or difficult cases, particularly in the sort of case where a boy was backward and it was not known whether this was due to inability to learn or to some temperamental difficulty. About 80 special examinations and reports have been made in these cases.

The physical tests employed have been used by trainers to assist them in grading certain athletes, particularly cross-country runners and tug-of-war teams. About 100 examinations of this sort have been carried out.

#### THE VALUE OF VOCATIONAL TESTS

A recent publication ("The Examination of Examinations") has shaken the confidence of many in the present form of scholastic examination, but it is often asked: "What is there to take its place?" So far as the entrance examination for Royal Air Force apprentices is concerned, I suggest that the answer is given here. It is: supplement the scholastic examination by other tests such as those described. (And it may be observed that such tests hold good for selection for any mechanical employment, and are easily adaptable to the requirements of any particular trade.)

Psychological tests have been compared with thermometers in that they fittingly replace fallible judgment by objective data, and will give constant readings regardless of who uses them. Tests of the sort described in this paper have corresponding advantages over existing methods of personal selec-

tion and examination. For example, their exact worth can be measured by mathematical methods; they require no writing, they contain no trick items; they have a standardised procedure and method of marking; no preliminary "swotting" can help; each question admits of only one correct response; specific abilities and capacities may be measured. If I may use the jargon of the financial columns, I do not know whether shareholders will consider that prospects of dividends such as those outlined here will merit a slight variation in capital distribution. But I suggest that psychological tests are to-day moving from the "speculative" into the "investment" category; indeed, the intelligence, mechanical aptitude, and two mechanical ability tests receive enough statistical support in this inquiry to be classed as "trustee stock."

I wish to thank the Air Officer Commanding, Halton Command, and his staff (particularly the principal education officer) for the kind assistance which has been given at every point, and also to thank the Industrial Health Research Board of the Medical Research Council, who have not only provided some of the tests, marked some of them, and carried out the statistical treatment of the whole examination, but also by their general co-operation have made this investigation possible.

## PARIS

(FROM OUR OWN CORRESPONDENT)

### DECLINE OF BREAST-FEEDING IN THE COUNTRY

THE recent appointment by the Academy of Medicine of a commission to investigate the decline of breast-feeding in France is largely due to the disturbing information collected by Dr. Lesage and Dr. Cruveilhier. They addressed themselves to medical practitioners in the country districts and in towns with a population of less than 5000, and invited not only data but comments thereon. The response was generous, and some 800 doctors answered. The burden of their replies was that faulty infant feeding in the country was the most important factor in the infant mortality, and was traceable to the abandonment of breast-feeding. In Normandy the few mothers who still suckle their babies are not farm workers but factory hands whose employers presumably make special arrangements for them. In another area it is calculated that only 5-10 per cent. of the mothers give their babies the breast, and when they do so it is only for two or three months. A general practitioner with an experience of ten years in his district had not known of a single case of breast-feeding by a farm worker. The explanations offered for this state of affairs by the medical profession are remarkably varied. Some see in it "a sort of moral crisis which rages among the peasants." Others find the mother of to-day anxious to enjoy the privileges she learnt to enjoy during the late war. The alleged fear of women to "compromise their aesthetics" is also mentioned as a factor in the case. They are accused of sacrificing breast-feeding to outings, the cinema, the motor-car, and the bicycle. Then there is the overwork for women on farms whence the male labourer has fled. The mothers have, in fact, so little time for eating and sleeping that there is none left for breast-feeding, and the fact that it is commoner in the winter, when there is comparatively little to be done in the fields, than in the summer seems to support this view. Dr. Lesage and Dr. Cruveilhier lay the blame in an evil concatenation of circumstances rather than on any inherent wickedness, beyond the ordinary, in women.

## TOO SUCCESSFUL TREATMENT OF A SPRAINED ANKLE

A general practitioner in the North of France, having mastered the by no means complicated treatment of sprains by the injection of novocain into the painful area, was consulted one Saturday by a motor driver who had fallen off a motor lorry and sprained his ankle. He had been able to drive his lorry back to the garage without excessive pain, but after a few hours his sufferings had been such that he had had to seek his doctor, who found slight œdema of one ankle, in which there was lively pain on movement about the joint. A sprain was diagnosed and a certificate to this effect was signed by the doctor with a view to insurance benefit. He then injected novocain locally, having learnt of Prof. René Leriche of Strasbourg what a remarkably effective procedure this is. A few minutes later the patient was no longer a patient—he could walk without pain. Next day, Sunday, he walked about freely, and on Monday morning he returned to work. But the doctor's account was not honoured by its recipient, an insurance society. The refusal to pay was backed by the intimation that the alleged sprain was apocryphal, that there had, assuredly, been no accident, and that its fictitious victim had been seen about on the day of the "accident," walking with perfect freedom. Under these circumstances the doctor's claim for a reward for his successful treatment could not be met, and he must be thankful if he escaped a charge of conspiracy to defraud the insurance society. The matter was referred to Prof. Leriche who willingly testified to the apparently almost miraculous effects of his treatment, and who warned insurance societies that if therapeutic successes were to be the signal for refusals to pay for them, the inducements to enjoy them might wane to the point of their not being wanted by the insured. He also remarked on the lack of psychological insight shown by the insurance society in question, for it is characteristic of the true malingeringer that his ailments are refractory to treatment, not that they vanish into thin air in response to a single injection. And if insurance societies persist in their error the insured will prefer the combination of pain and stiffness with compensation to prompt recovery without it. It is wonderful how tolerable the discomforts of a sprained ankle can become if they are mitigated by insurance funds and relaxation by one's own fireside.

## TYPHOID FEVER IN FRANCE

In the *Revue d'Hygiène* for May, Prof. G. Dubreuil of Bordeaux reviews the causes of the high typhoid rate in France, and of the measures most likely to reduce it. In 1906 there were 14 notified deaths from typhoid fever per 100,000 inhabitants, and in 1932 the corresponding figure had been reduced to 3.8. But France still enjoys an unenviable reputation in this respect when compared with several other countries, her 3.8 per 100,000 in 1932 comparing badly with 1.2 for Germany in the same year and 6 for England in 1933. An instructive feature of Dubreuil's study is his charting of the different French administrative areas according to the level of their typhoid death-rates. This geographical survey throws into lurid relief the coastal districts, apart from occasional water-borne epidemics, the disease seems to be more or less permanently settled in certain well-defined areas, and the most important of these areas are to be found on the Atlantic and Mediterranean seaboard. The predilection of typhoid fever for the coast is reflected in the mortality returns of the large towns on the coast and inland respectively. Thus Toulon and Bordeaux in the period

1926-31 had typhoid mortalities of 18.2 and 17.4 respectively per 100,000, whereas the corresponding figure for Lyons was 5.6, and for Rheims only 1.9. In France the urban typhoid death-rate is higher than the rural death-rate from the same cause, although urbanisation may often be said to be synonymous with a comparatively pure drinking-water. The explanation of this phenomenon is probably to be found in large part in the comparatively important consumption of shell-fish in the towns. This explanation would also account for the preference shown by the typhoid bacillus for the coastal districts. Man has become fussy over uncooked and unwashed fruit and vegetables, but he remains loyal to uncooked shell-fish; there seems to be veritable desecration in the cooking of an oyster. Dubreuil's remedy for this state of affairs is largely administrative and educational; all concerned with the shell-fish industry should be taught to take the necessary precautions and be weaned of the notion that their hygienically unhampered means of livelihood must be maintained regardless of the welfare of the rest of the community. He concludes with a statement casting doubt on the efficacy of antityphoid inoculation, as at present practised, against infection through shell-fish.

## BUDAPEST

(FROM OUR OWN CORRESPONDENT)

## THE PREVENTION OF VENEREAL DISEASE

THE Teleia Society, founded in Hungary in 1893 by Profs. Feleky, Temesváry, and Török, claims to have been the first of its kind in Europe. Initially consisting only of an out-patient clinic offering free treatment for venereal disease, it has been stimulated by the great increase in these diseases after the late war to establish dispensaries in several towns and to introduce widespread and effective propaganda throughout the country. Dr. Aladár Emödi, chief physician of the society, has arranged a display of instructive films, which was attended by 150,000 of the public; 500,000 postcards and pamphlets have been distributed among patients. A monthly journal has a circulation of 3000-5000, and 17 booklets have been published. Other antivenereal work is being done by the National Social Insurance Institute and other similar organisations, and the Stephanie National Association helps to provide dispensaries. Much propaganda is spread by the Institute and Museum of Social Hygiene, by frequent exhibitions held in Budapest and in the country, and also by Sunday lectures in the museum. All these measures show that the prevention of venereal diseases is very well supported in Hungary notwithstanding the very grave economical position of the country.

## PUBLIC HEALTH IN THE ECONOMIC CRISIS

Dr. Georg Gortvay, director of the Institute and Museum of Social Hygiene, in an elaborate study, has established the fact that the worst period of the economic crisis, 1928-34, resulted in a greatly reduced consumption of staple foods. The reduction in wheat was 13.3 per cent., in potatoes 8.3, sugar 3.0, meat 18.2, and in milk 30.8 per cent. The annual consumption per head in wheat and rye was 253 kilos, potatoes 150 kg., sugar 9 kg., meat 16 k.g., and in milk 14.4 litres (3.2 gallons). The fall in the consumption of staple articles went hand in hand with the deterioration of earning conditions as well as with the increase in the financial burden of the public. The agricultural

wages fell during this period by 40 per cent. It is a distressing symptom and characteristic of the social position of agricultural labourers that their daily food allowance was 12-14 fillér (a penny), when we consider that this small sum is not the equivalent of even a kilogramme of bread, and a labourer needs at least half a kilo a day. Dr. Gortvay established that the nutrition of the rural population is poor in vitamins, and that this is related to the spread of tuberculosis. His investigations show therefore that in relation to the work performed the nutrition is lacking in quantity as well as in quality.

But the nutrition of the rural child population is also deficient. It was established from the analysis of 2600 urban and 2900 rural school-children, that in the country food is monotonous and badly selected; vegetables are absent in the diet of 19 per cent. of the urban and 37 per cent. of the rural children. One would expect the contrary, but the peasants are forced, by the good prices that they get, to sell their vegetables in the town markets. Meat was lacking from the diet of 15 and 31 per cent. of the children in town and country respectively. Another investigation revealed that the rural child has to be satisfied with only one dish at lunch and dinner, usually of potatoes, bean soup, cooked vegetables, or farinaceous food. For breakfast he has a cup of milk, coffee, or tea, a piece of stale bread, or nothing at all; there are again no two-course breakfasts. Industrial labourers spend on food on an average 45 per cent. of their income. Among unemployed workmen, the daily food quota dwindles in direct proportion with the number in the family. Hand in hand with the deterioration in nutrition goes the increase in gastro-intestinal disease. During the period 1928-34 the medical officers of health at Budapest reported a 145 per cent. rise of patients requiring free treatment.

#### CASE OF GENERALISED PYODERMIA CURED WITH X RAYS

Dr. Haas, senior physician in Csakova, Banat, describes the case of a secondary school student, aged 15, who fell ill with scarlet fever. Although the disease was very severe from the beginning no complications at first emerged. When skin desquamation began, however, there was intense itching, which, on account of the neuropathic constitution of the boy, produced exaggerated scratching. Erythematous and bullous rashes and purulent vesicles appeared, which spread over the whole skin in a few days and displayed the uncommon but characteristic picture of impetiginous eczema and generalised pyoderma. All the drugs that are reputed to be effective in such cases proved futile. The boy had gradually rising fever and became very ill. In the last resort they applied X ray irradiation, which brought a surprisingly quick and prompt healing.

Haas irradiated the anterior and posterior surfaces of the body at two sittings. He used a filter of 1 mm., the dose being 15 erythema doses. The intolerable itching, which caused sleeplessness, ceased after the lapse of 24 hours. Since then Haas has applied small doses of X rays to all kinds of pyogenic dermatoses and to furunculosis, and the results have been just as reassuring.

#### SALVARSAN TOLERANCE IN EARLY CHILDHOOD

L. Dobszay and A. Bános have found in previous experiments that if infants are given an arsenobenzol preparation intravenously in exactly proportionate doses the arsenic curve of the blood differs from that of adults. In infants about 40 per cent. more arsenic leaves the circulation within the first half hour than

in adults. Searching for the cause of this they found that the final elimination of arsenic is identical in both groups, and therefore they had to assume that the arsenic surplus disappears only into the tissues. It may be that diffusion, or the mechanism regulating diffusion, is increased, or that the absorptive power of the tissues is relatively greater in children. The former could not be proved, although very careful tests were made. Nothing therefore remains, say Dobszay and Bános, but to accept the cause of the above difference as a difference in the cumulative power of the tissues, the more so as their investigations proved that the reticulo-endothelial system of infants accumulates the arsenobenzols much more vigorously than in adults, in whom this process is much slower, and it is this that explains the greater tolerance.

#### NICOTINE POISONING IN AN INFANT

Dr. Irene Greiner has reported a case of nicotine poisoning in a baby of three weeks, the vehicle being the mother's milk, for her daily tobacco consumption amounted to 35-40 cigarettes. The prominent symptoms of the intoxication were restlessness and sleeplessness, very frequent vomiting, severe colic, loss of appetite, and pallor. The animal experiments of Hatscher and Crosby, and numerous tests on lactating women, have revealed that the mammary gland can excrete nicotine. From this it is concluded that it is wise for mothers to give up smoking during lactation, or at least considerably to curtail it.

The lecturers and professors of the Budapest University arranged a well-attended post-graduate course for a fortnight in May. The lectures were held in Hungarian, German, and French. The Hungarian Government allowed to those attending the course a 50 per cent. reduction on all the State railways.

## UNITED STATES OF AMERICA

(FROM AN OCCASIONAL CORRESPONDENT)

#### THE SPRING CONFERENCES

MOST important of medical and scientific conferences to the practising physician is the annual meeting of the American Medical Association. It was held this year at Kansas City and of the 6824 doctors who registered their attendance more than one-third came from the contiguous States of Missouri and Kansas. It is estimated that double the number of registrants were present in the auditorium to hear welcoming speeches from the governors of these two States.

The address of the retiring president to the House of Delegates and that read for the incoming president, whose serious illness prevented his attendance, alike reflected the complacency of the leaders of the profession in this country at the conservation of the status-quo or, to use the words of the retiring president, Dr. James S. McLester, "the preservation, unimpaired, of established methods of practice, methods by which American medicine has reached its present pre-eminent position." The president for this year, in his tour of the country during which he has spoken before some 8000 physicians, has found that the majority of these are "pleased and gratified to hear that the aim of the American Medical Association is to preserve the individual private practice of medicine, with free and open competition among physicians and the maintenance of personal relationship of doctor and patient." Yet beneath this complacency and self-gratulation there are certain symptoms of inquietude. Dr. McLester pointed

out that the disaster which has overtaken our colleagues in England, as elsewhere in Europe, came "at the end of a long series of other so-called social reforms," and that the control by government in this insidious manner of the practice of medicine "once established has never been relaxed." The train of events, the so-called social reforms, which preceded the *krankenkassen* system in Germany and the panel system in England, is already well started in this country, he pointed out, naming as terrible examples the provisions of the Social Security Act for maternal welfare and for old age pensions. "Will the politicians of the near future," he asked, "anxious to carry government subsidies still further, extend their control, as politicians have already done elsewhere, to medical care?" Now the Social Security Act is the product of a Democratic administration. The Governor of Kansas, on the other hand, is at present the prime favourite for nomination as presidential candidate on the Republican ticket. He showed keen political insight and was rewarded with a stirring political ovation when he declared: "Medicine will not willingly be made the servile instrument of politicians or the instrument of domineering bureaucrats."

It would be entirely unjust to leave the impression that the Kansas City meeting had not also its scientific aspect. In the section on tuberculosis Dr. James Alexander Miller attributed the decline in tuberculosis mortality largely to the development of racial immunity. In other sections were described a new method of removing hitherto inaccessible brain tumours, a new use for "artificial fever" in the treatment of chorea, the use of helium in the treatment of asthma, and so on. A popular educational feature was Dr. De Lee's moving picture of the forceps operation.

Members of the American Psychiatric Association had a short journey from Kansas City to their own convention in St. Louis. They assembled there 1800 strong. Dr. C. O. Cheney, the retiring president, effectually "debunked" the popular theory that insanity results from the stress and strain of modern life. This doctrine he showed was advanced as early as 1734. The new president of the Association is Dr. Macfie Campbell who has been for long a leader in the mental hygiene movement.

The American Laryngological, Rhinological, and Otolological Society met at the end of May in Denver, Colorado. Bronchoscopists went from Denver to Detroit for the ninth annual meeting of the American Bronchoscopic Society. No less than seven national associations in different medical specialties are to meet this month.

Important announcements of medical research are not always heard for the first time, however, at physicians' meetings. The American Chemical Society which also met in Kansas City this spring again challenged the propriety of substituting purified derivatives for the original cod-liver oil. Just as this oil was found to contain vitamin D as well as vitamin A, and to be of value for its content in A as well as for its supply of D, so now there is evidence of other important nutritive constituents which have not yet been isolated. The possibility of purifying waters that contain fluoride and cause "mottled enamel" on so many American teeth by the use of aluminium hydroxide is another chemical contribution of importance to public health.

#### THE NATIONAL LEAGUE OF THE TUBERCULOUS

Some 50,000 cases of advanced pulmonary tuberculosis are discharged from our sanatoria each year

Their subsequent fate has aroused hitherto very little interest beyond that of the statisticians who calculate that 52 per cent. of them suffer a relapse and die within two years. No serious attempt is made by any governmental authority to provide working conditions adapted to the working capacity of these discharged patients or to lessen in any other way the probability of relapse and death. Private efforts, such as the work of the Altroschop in New York, though gallant and successful, are small in scope and pitifully few. The challenge of this grave social need has now been taken up by the tuberculous themselves, who have formed a National League of the Tuberculous with headquarters at Woolsey Station, Astoria, New York. Membership dues are \$1 per annum which includes subscription to the official organ *The Voice of the Tuberculous*. The League will air the grievances and protect the interests of all who are handicapped with this disease and will urge two specific solutions: (1) the provision of pensions under the Security Act; and (2) the provision of village settlements. The origin of the League is explained in the first number of the *Voice* as follows:—

"Outside organizations, no matter how well-meaning they may be, are an affliction rather than an aid to the tuberculous. Professional sympathizers capitalize on the misfortunes and hardships of the tuberculous in order to raise funds. Their sob-stories and tear-jerking publicity increase hypochondria and the unhealthy and morbid fear of tuberculosis. Whoever has been touched by the disease finds himself stigmatized and marked for exile. He is unemployable because of pity. Employers are afraid he will break down again and become a liability. Fellow workers are afraid they will catch 'consumption' from his presence. And our charitable organizations give him the choice of starvation or the poor farm.

"The tuberculous have learned that their only true friends are their fellow victims. Their only hope for aid in rehabilitation and a normal life is to join hands in a cooperative effort to help each other without depending upon charity or pity. And with this single-minded purpose of forming a national union for cooperative self-help, The National League of the Tuberculous has been organized."

The organisers while nourishing this admirable spirit of independence and self-help are nevertheless willing to accept contributions from well-wishers of their movement.

## MEDICINE AND THE LAW

### Trespass for Want of Patient's Consent

Mr. Justice Swift's decision last week in *O'Shea v. Moyce and Donston* was a reminder of the risks of operation without the patient's specific consent. The surgeon may often rely upon the understanding, normally an implied condition of the legal relationship of the parties, that the patient gives implied consent to all such actions as professional skill and judgment may deem necessary. It may be possible to obtain beforehand a definite authority in writing for the performance of some named operation; but precise knowledge is not always available and emergencies may occur. An unauthorised operation is technically an assault or trespass. The practitioner runs a risk of a claim for damages.

In Miss O'Shea's case last week it was alleged that a dentist had extracted teeth without permission. She had a broken tooth which disfigured her mouth; it seemed likely that other dental treatment was needed. Her panel doctor examined her mouth and certified that she ought to see a dentist. The defendant dentist recommended that all her 16 upper teeth and two of the lower teeth should be extracted.

According to the judge's findings, Miss O'Shea was upset by this information. She asked whether she really need lose all these teeth and was told that, while they were not all bad and while some could be saved, she would have to come back later and have all the fuss and bother over again unless she had them all out now. She was persuaded, said the judge, by this mention of future fuss and bother and she attended at the defendant's surgery. On the first occasion ten upper teeth were extracted while she was under gas. When she recovered consciousness she complained that another tooth was still aching; the dentist thereupon extracted one more; he told her that further teeth were still to be removed. At the end of this first visit, said the judge, nothing had happened to which Miss O'Shea had not assented. But afterwards she said that, though one or two teeth might have needed stopping or taking out, the wholesale clearance was quite unnecessary. She had accepted his advice but the advice was negligent. A week later she paid her second visit for the removal of the teeth not previously extracted. On this occasion, Mr. Justice Swift held, no fresh advice was given her and no fresh consent obtained; the remaining teeth in the upper jaw and the two teeth in the lower jaw were to be taken out. But when she recovered consciousness, she found that all the teeth on the right side of the lower jaw had been removed. For this, in the opinion of the court, there was no justification. There had been ample opportunity for the dentist to come to the conclusion that all these teeth should come out. He could have asked the patient or her mother before giving the gas; he could have waited till the patient recovered consciousness. "To go and take out all those teeth without a word and without asking permission" his Lordship considered to be a trespass such as entitled Miss O'Shea to damages. The patient told her mother and they went back to the dentist who explained that the teeth had been pyorrhetic. The judge accepted the evidence given on behalf of the plaintiff that Miss O'Shea's mouth had shown no signs of pyorrhœa. He considered she had been improperly advised about her upper teeth and had suffered a trespass in the removal of her lower teeth without her consent. He gave judgment in her favour for £250.

The legal doctrine of the patient's implied consent, therefore, did not cover the case of professional treatment involving pain and permanent disability. It was the practitioner's duty to furnish the patient with information of the proposed action and with the opportunity to give or refuse consent. Mr. Justice Swift's decision suggests that in dental practice no such emergency is likely to arise as would relieve the practitioner of his duty to obtain the patient's consent beforehand. The dentist who assumes that he has been given a free hand to do his best may find that the law regards him merely as a trespasser.

#### What is Lysol Soap?

How much lysol should there be in a substance sold as "lysol soap"? In *Stott v. Green and Stott v. Henshaw* last month the Salford stipendiary had refused to convict the retailer of "medicated lysol soap" which contained only 0.1 per cent. of lysol. Proceedings had been taken under Section 2 (1) of the Merchandise Marks Act, 1887, and the city analyst had given evidence that the soap, to justify its description, ought to contain at least 2 per cent. of lysol. The retailer contended that the soap was honestly compounded and did contain some, though only a minute amount of, lysol. The magistrate held

that he had no power to fix a standard; if he had the power, he would have fixed 1 per cent. On appeal to the High Court the Lord Chief Justice said the magistrate was wrong in thinking that there could be no conviction so long as the soap contained any trace of lysol. The case was sent back to the magistrate with a direction to find that the offence was proved.

In *Dryden v. Stewart and the Surrey County Council* on which Mr. Justice Finlay gave judgment last week (see p. 1378) Dr. John Stewart had the assistance of the London and Counties Medical Protection Society.

## LISTER INSTITUTE OF PREVENTIVE MEDICINE

UNDER the general control of Prof. J. C. G. Ledingham, F.R.S., who is also director of one of the four main departments of the Institute, some 30 workers are engaged in medical research at the Lister Institute. The department of bacteriology, serology, and experimental pathology absorbs 17, including 1 in the division of protozoology and 4 in the division of nutrition; in the department of biochemistry Prof. R. Robison, F.R.S., has 6 colleagues; Dr. G. F. Petrie, bacteriologist in charge of the department for the preparation of therapeutic sera (at Elstree), has 3; and Dr. D. McLean, also at Elstree, is solely responsible for the department for the preparation and study of vaccine lymph. Apart from these members of the staff the hospitality of the Institute is given to many holders of research scholarships and voluntary workers.

In the annual report of the governing body an account is given of the varied investigations now in progress in all these departments. A few of them are summarised below.

#### STUDIES ON VIRUSES

During the past five years considerable attention has been paid by workers on virus problems at this Institute to fundamental studies on the elementary bodies which are generally believed to constitute the sole effective ætiological agents in all virus diseases. The fact that these bodies can now, by various procedures, be separated from crude virus-containing material in a state of comparative purity has greatly facilitated the study of their ætiological relationships and even in those virus diseases such as chicken-pox and herpes zoster, that so far have defied attempts to secure their transmission to laboratory animals, it has been possible by serological analysis, particularly agglutination experiments with highly concentrated suspensions, to demonstrate not only an ætiological connexion between the elementary body and the virus disease but also in some cases to explore the nature of the affinities, sometimes quite unexpected, between one virus and another.

The antigenic structure of the virus of *vaccinia* has been under investigation by Dr. M. H. Salaman (Beit Memorial Research Fellow) since October, 1935. Prof. Ledingham, in collaboration with Dr. W. E. Gye, of the National Institute for Medical Research, reported in 1935 the results of experiments which indicated that the filtrable tumour-exciting agents of the Rous and Fujinami fowl sarcomata were probably particulate in nature. Dr. C. R. Amies has obtained further evidence that points to the same conclusion.

Microscopical examination of actively tumour-

exciting, fowl protein-free suspensions by the method of dark-ground illumination reveals the presence of numberless particles of slightly varying size. Further investigations of the properties of purified tumour-exciting suspensions are in progress.

Prof. Ledingham has for some time been engaged in a study of the relationship between the filtrable viruses of *rabbit myxomatosis* (Sanarelli, 1898) and *rabbit fibroma* (Shope, 1932), in view of Shope's observation that rabbits which had recovered from the fibroma were to a high degree protected against the fatal issue that almost invariably follows the inoculation of the virus of myxomatosis.

Studies on acute rheumatism started by Dr. Amies and his colleagues, Drs. Schlesinger and Signy, which pointed very strongly to a *virus agent in acute rheumatic fever*, are now being carried on by Dr. G. H. Eagles with the assistance of Dr. P. R. Evans and of Mr. A. G. Timbrell Fisher, whose operative procedure in the treatment of rheumatoid arthritis gives access to abnormal synovial tissue. They find that pericardial and pleural exudates and joint fluids from acute rheumatic fever, and joint fluids and synovial membrane from acute rheumatoid arthritis have yielded suspensions of bodies which are indistinguishable from elementary bodies demonstrable in similar suspensions from recognised virus diseases. Serological studies are being undertaken to support observational evidence and it is hoped thus to confirm the findings in acute rheumatic fever, to establish a possible virus aetiology in rheumatoid arthritis, and to investigate the possibility of a relationship between acute rheumatic fever and acute and subacute rheumatoid arthritis by cross-agglutination tests.

Dr. E. Weston Hurst has completed a study of the course of infection with *equine encephalomyelitis* virus. Unlike many neurotropic viruses, this virus does not reach the central nervous system by way of the peripheral nerves: during its circulation in the blood stream it may sometimes be detected on the nasal mucosa, whence, apparently, it reaches the brain by the perineural lymphatics of the olfactory nerve. Such a mode of infection of the nervous system was previously unsuspected, except, of course, when viruses are introduced directly into the nose; in nature the equine encephalomyelitis virus is one of a group transmitted by biting insects.

The investigation undertaken by Dr. Eagles in collaboration with the Danish State Serum Institute, Copenhagen, into the neutralising value of samples of serum from cases of *poliomyelitis* at different periods following recovery from the disease has been completed and the results obtained will shortly be published.

Samples of pooled serum from paralytic cases taken on an average of 29 days after recovery showed a low titre of protecting antibody. From non-paralytic cases taken about the same period a slightly higher value was obtained. In these cases sera from patients belonging to blood-group "B" were tested in one pool. This pool was shown to have a very high titre of protecting antibody. A pooled serum from abortive cases taken 13 days after recovery also showed a very high level of protective antibody. Cases tested at a later date—approximately four months after the onset of the meningitic state—showed on the whole a considerably lower titre of protective antibody. While it is impossible to generalise on a limited number of tests it would seem that considerable variation in antibody production occurs amongst individuals following recovery and that the highest titres are to be expected early in convalescence.

It would be of great value in such investigations

if there were available a dried standard convalescent serum for assessing comparative value of sera tested by neutralisation experiments in monkeys.

Dr. E. Klieneberger (Jenner Memorial Research Student) has continued her work on *pleuropneumonia-like organisms* as symbionts of certain bacteria.

#### SEROLOGICAL STUDIES

Serological studies on the antigenic constitution, virulence, and immunising properties of bacteria are being pursued. Dr. A. Felix, with Miss R. M. Pitt and with the collaboration of Captain S. S. Bhatnagar (I.M.S.), has continued the investigation of the "Vi" antigens of *S. typhi* and of other salmonella species. The method of immunising horses for the preparation of *therapeutic antityphoid serum* has recently been simplified by the use of alcohol-treated suspensions containing both the "Vi" and the "O" antigens, since the "Vi" antibody elaborated in response to immunisation with alcohol-treated suspensions is as potent in protective action as that resulting from immunisation with the "natural" "Vi" antigen contained in the live virulent bacilli. With the recognition of the special importance of "Vi" antigen in antityphoid immunity, the study of methods of vaccine preparation which should leave this antigen intact and as effective as possible becomes desirable. Dr. H. Schütze has demonstrated by experiments with mice that for prophylactic purposes the old-established method of heat-killing and phenol-preservation is as efficient as any of the alternatives he has tested.

#### ENDOCRINOLOGY.—PROTOZOLOGY

Dr. V. Korenchevsky, with the assistance of Mrs. M. H. Dennison and the voluntary coöperation of Dr. S. Levy-Simpson and Mrs. I. Brovsin, has continued to study the effects of the *sexual hormones* and of *adrenalectomy*. Joint experiments with Miss E. M. Hume on the effect of sexual hormones on vitamin-deficient rats and with Dr. J. M. Gulland on the gonadotropic hormones of the suprarenal cortex are also in progress. The coöperation with Prof. Ruzicka has been continued in the investigation of male sexual hormones.

Experiments are being made by Miss Muriel Robertson, D.Sc., with the aim of elucidating some of the principles underlying the *reactions of protozoa to various drugs* and poisonous substances. As a test object for this purpose, a ciliate (a glaucoma, probably *Glaucoma piriformis*) has been isolated in pure bacteria-free culture. This organism has been cultivated in standardised counted cultures and very regular results have been obtained. The reactions of glaucoma to inorganic arsenic ( $As_2O_3$ ) have been investigated for some months with the result that acclimatisation has not been found to take place as a consequence of cultivation in sublethal concentrations of the substance. In time-exposures to lethal concentrations there is a certain advantage in survival on the part of cultures previously exposed in this same type of experiment, but not on the part of strains which had previously been cultivated in non-lethal amounts of the substance. At present it seems likely that simple selection of the more viable individuals, rather than acclimatisation is the correct interpretation of the somewhat greater viability.

#### NUTRITION

A collective investigation is being arranged by the *vitamin-A* subcommittee, by means of which the results of spectrophotometric examination of certain

selected materials are to be compared with those derived from biological tests carried out in several different laboratories.

The anomalous behaviour of certain forms of *vitamin D*—e.g., irradiated ergosterol and cod-liver oil—when administered as antirachitic agents to certain species (e.g., poultry) has introduced a complication into the interpretation of vitamin-D standardisation, seeing that the vitamin-D standard is irradiated ergosterol and the usual biological tests are carried out on rats. The most probable explanation lies in the discovery by Windaus and others of the existence of more than one form of vitamin D, that in cod-liver oil being different from that present in irradiated ergosterol, and birds being relatively insensitive to the second form. Miss Hume has collected the existing scattered information in the literature upon this subject with a view to its publication.

It was demonstrated last year, on a laboratory scale, that it was possible to add synthetic *ascorbic acid* to fruits and vegetables before canning without incurring great losses in the vitamin during the processing. Under conditions resembling those employed in large-scale canning equally favourable results were obtained.

#### WORK ON THE VITAMIN-B COMPLEX

The relation of the two constituents of *vitamin B<sub>2</sub>* (flavin and vitamin B<sub>6</sub>) to the skin lesions occurring in rats deprived of this vitamin has been studied by Miss A. M. Copping, who has confirmed the conclusion of György that vitamin B<sub>6</sub> prevents the (a) symmetrical florid dermatitis ("rat pellagra") and flavin the (b) skin affection involving loss of hair without swelling, and an exudate of serous fluid from eyes and nostrils.

The discovery of the composite nature of vitamin B<sub>2</sub> has led to a reinvestigation of wheat, maize, and their milling products; Miss Copping has found them good sources of vitamin B<sub>6</sub>, but poor in flavin.

These results indicate that lack of vitamin B<sub>6</sub> cannot be connected with the aetiology of pellagra, since the maize diets on which populations suffering from endemic pellagra subsist are rich in this vitamin. There would seem to be a definite nutritive advantage in wheat over maize in the possession of a greater amount of flavin, seeing that the foodstuffs found by Goldberger and his colleagues to be preventive and curative of pellagra were those rich in flavin. Recent clinical trials reported from the United States have failed, however, to demonstrate any curative effect for pellagrins of administration of pure flavin.

Laboratory investigations have so far failed to explain the relative immunity from serious deficiency disease existing among populations whose staple diet is wheat and bread made from white flour, when these are compared with populations subsisting too exclusively on maize or rice, which are subject to pellagra and beri-beri respectively.

The content in these cereals of the B-vitamins has not shown differences large enough to account for the observed difference in nutritive value, although administration of these vitamins (in the form of yeast) has proved curative and preventive for both pellagra and beri-beri. It seemed possible that the use of yeast in the manufacture of bread from wheat might provide the clue. Miss M. H. Roscoe and Miss Copping, with the kind and generous co-operation of Dr. Kent-Jones, and of Messrs. Chitty, millers, of Dover, have procured special samples of wheat and white flour, and bread has been baked from these by different methods using varying amounts of a standard yeast.

The amount of the B-vitamins (B<sub>1</sub>, flavin, and B<sub>6</sub>)

in the various ingredients and in the finished breads is now being estimated, the aim being to determine what proportion of the vitamins in the finished product is derived from the added yeast and whether any synthesis takes place during the fermentation process.

#### ANTI-MENINGOCOCCUS SERUM

The therapeutic action of *anti-meningococcus serum* is being studied in the department for the study and preparation of therapeutic sera. The pathogenic action of the meningococcus is apparently due to the intracellular poison which is liberated in the course of the natural disease and which can be separated from the coccal bodies under experimental conditions.

Work carried out by Dr. Petrie has led to the conclusion that this toxic substance is not antigenic and that, therefore, the therapeutic efficacy of the serum cannot be ascribed to an anti-endotoxin and is probably wholly dependent upon an antibacterial mechanism. Formerly very large intraperitoneal doses of cocci were necessary in order to produce a fatal infection in mice and it was difficult to dissociate the pathogenic effects due to the endotoxin and to the coccal invasion. It now appears that some freshly isolated strains are highly virulent and that the virulence of other strains is enhanced by incorporating mucin prepared from the gastric mucous membrane of the pig in the dose of the coccal suspension which is injected into the mouse; the lethal dose may contain as few as 10–20 cocci. By this means it has been found possible to arrange protective experiments which show that immune-sera from the horse can neutralise the pathogenic effect of many multiples of the lethal dose of living cocci. The mode of action of the mucin is not understood but it may be presumed to involve protection of the coccus from the phagocytic cells of the host. Dr. Petrie has begun work on the factors which influence the virulence of the meningococcus while it is living under saprophytic conditions and while it is multiplying in the tissues of the experimental animal.

Fuller knowledge of the conditions that are requisite for maintaining the virulence of this micro-organism at a high level will simplify the application of methods of assaying the potency of anti-meningococcus serum.

#### INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED JUNE 6TH, 1936

*Notifications.*—The following cases of infectious disease were notified during the week: Small-pox, 0; scarlet fever, 1613; diphtheria, 709; enteric fever, 30; pneumonia (primary or influenzal), 679; puerperal fever, 35; puerperal pyrexia, 115; cerebrospinal fever, 16; acute poliomyelitis, 10; acute polio-encephalitis, 2; encephalitis lethargica, 2; continued fever, 1 (Tottenham); dysentery, 13; ophthalmia neonatorum, 76. No case of cholera, plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the London County Council on June 12th was 4798, which included: Scarlet fever, 1057; diphtheria, 724; measles, 1780; whooping-cough, 533; puerperal fever, 15 mothers (plus 10 babies); encephalitis lethargica, 283; poliomyelitis, 2. At St. Margaret's Hospital there were 28 babies (plus 15 mothers) with ophthalmia neonatorum.

*Deaths.*—In 122 great towns, including London, there was no death from small-pox or enteric fever. 39 (11) from measles, 9 (3) from scarlet fever, 28 (7) from whooping-cough, 30 (4) from diphtheria, 36 (17) from diarrhoea and enteritis under two years, and 29 (6) from influenza. The figures in parentheses are those for London itself.

No great town reported more than 2 deaths from measles. Liverpool had 4 fatal cases of whooping-cough, Birmingham 3. Deaths from diphtheria were reported from 18 great towns; 5 from Hull, 3 from Liverpool.

The number of stillbirths notified during the week was 276 (corresponding to a rate of 45 per 1000 total births), including 53 in London.

## PANEL AND CONTRACT PRACTICE

## AN AMERICAN VIEW OF HEALTH INSURANCE

It is unfortunately true that many American writings designed to impart instruction on European health insurance systems contain errors of fact, and to this must be attributed the misconceptions of health insurance that are so prevalent in America. Such, for instance, as the belief that the English system is on the verge of bankruptcy; that it is detested by the insurance doctors, who would gladly be rid of it; and some other delusions strange enough to appeal to the sense of humour which, in spite of a widespread American belief to the contrary, is an important part of the English character. Such criticisms cannot, however, be brought against the latest American book on health insurance, Dr. I. S. Falk's "Security against Sickness."<sup>1</sup> Dr. Falk had exceptional qualifications for his task. He was in charge of the field work carried out by the Committee on the Costs of Medical Care during their five years' study of the conditions under which medical care is given, or not given, in the United States—the most complete study of the economics of medical practice ever undertaken—and he has made a special study of European health insurance both by an intensive scrutiny of documents and by personal visits to eight European countries. The result is a valuable book: informative, eminently readable, and marked by a critical acumen that inspires confidence in the author's judgment.

Dr. Falk approaches health insurance from the point of view from which it is generally regarded by students in America and other countries where it has not yet been introduced. In Europe health insurance began as something in the nature of a savings bank. Its aim was to provide money for disabled wage-earners. Medical care came later and long held a secondary position. With the advance of medical science, which not only increases the efficiency of medical treatment but makes it more expensive, it has become of primary importance, even from an economic point of view. The inquiries of the Committee on the Costs of Medical Care show that the cost of securing adequate medical treatment by private arrangements imposes an economic burden heavier than loss of earnings due to incapacity for work. Hence in the new countries health insurance is regarded chiefly as a means of providing medical care, and the payment of cash benefits during periods of incapacity as a function to be discharged by a separate authority or by the authority administering unemployment insurance. The health insurance system adopted last March by the legislature of British Columbia, the first British dominion to introduce compulsory health insurance, gives no cash benefits but is limited to the provision of medical care.

The changes in the German health insurance system made by the National Socialist government are duly set out in this book. The insurance societies (*Krankenkassen*) have been integrated as elements of a single system, and by an equalisation fund the serious inequalities in the benefits given by the various societies have been lessened if not removed. The administration of the societies has been transferred from the old management committee to a "leader," one for each society, appointed by the government,

who is assisted by an advisory board containing a doctor nominated by the local medical organisation. Thus, for the first time, the medical profession has secured representation on the bodies administering sickness insurance in Germany. The State contribution to the cost of the system has been discontinued, and the employer's contribution raised from one-third to one-half of the joint contribution of employer and employee. The sanatoria and other institutions and the preventive services of the *Krankenkassen* have been transferred to the invalidity insurance administration, and the *Hartmannbund* and other medical organisations have been dissolved and exclusive legal status has been given to a new medical body, the *Krankenkassenärztliche Vereinigung Deutschlands* (K.V.D.), which is under the supervision of the Ministry of Labour. Insurance practice can be undertaken only by members of the K.V.D., and "non-Aryans" are excluded from membership. Contracts for medical service are no longer made between the societies and individual doctors but are negotiated centrally between the insurance authorities and the K.V.D., which by its local branches distributes among the doctors of the various areas the sums available for medical remuneration.

Of special interest is the account given by Dr. Falk of the French method of medical remuneration, the *entente directe*, by which the doctor's fee for each "medical act" is paid by the patient, who is reimbursed part of the cost by his insurance society. The chief object of this method is to prevent undue calls upon the doctors' services, and it exercises an attraction on the medical profession in countries in which the adoption of compulsory health insurance seems on the way to become a matter of practical politics—in New Zealand, for instance, where the introduction of a health insurance scheme appears to be imminent. Dr. Falk's account of the method is not likely to encourage its adherents. In practice it requires a vast amount of official checks and safeguards, and it has not tended to enhance the prestige of the medical profession in the community. This is largely owing to the wide discrepancy between the fee schedule of the insurance societies and the fees charged by the doctors, which are based on the scale fixed by the local medical association. The patient is reimbursed by his society 80 per cent., not of the doctor's fee, but of the fee allowed for the service in the society's schedule, which is usually much lower. The schedule fee of the Paris societies for a day visit is 17 francs, but the minimum fee of the medical association is 30 francs, so that the patient's reimbursement (fr.13.60) forms only 45.3 per cent. of the fee actually paid. In French insurance practice there is still the barrier of a substantial fee interposed between doctor and patient. The method was adopted at the insistence of the doctors who, now that they have secured it, are not sure that it is what they really want. As Dr. Falk observes:

"By the victory of dictating the system of remuneration and of assuring all patients completely free choice of doctor the French doctors achieved stringent limitation of fees, a complex and cumbersome fee schedule, necessity for close administrative supervision, conflicts with the insurance authorities, and a considerable loss in public esteem. The confusion which has followed upon the Pyrrhic victory seems to have exceeded what occurred in Germany with salaries, per-capita payments and fee schedules, and is vastly in excess of what has been customary in Great Britain under per-capita payments."

<sup>1</sup> New York: Doubleday, Doran and Co. 1936. \$4.

It must be admitted that in some respects the British scheme emerges in an unfavourable light from Dr. Falk's comparative analysis. After 23 years it is still mainly concerned with the provision of cash benefits. Of the total expenditure only 38 per cent. is devoted to providing medical care, as against 60 per cent. in France, 69 per cent. in Germany, and no less than 80 per cent. in Denmark. Unlike most continental systems it provides small specialist or institutional treatment, no nursing, or laboratory aids to diagnosis; it does nothing for the dependants of the insured, and its maternity provisions are limited to a cash payment on confinement. But against these inadequacies must be set the inestimable

advantage that the system has from near the beginning been worked with the cordial co-operation of the medical profession, and in this respect it stands almost alone. Moreover, though it is true that as regards the range of medical benefit the system is where it was at its inception, great advances have been made in the health work of the local authorities—e.g., in providing treatment for tuberculosis and venereal diseases, and maternity and child welfare services; and the Local Government Act, 1929, has led to further important advances. All this is recognised in Dr. Falk's book, which may be studied with profit by all who, whether as doctors or administrators, are engaged in the working of national health insurance.

## PUBLIC HEALTH

### ISOLATION OF SCARLET FEVER IN THE HOME

BY DUNCAN FORBES, M.B.E., M.D., D.P.H.

MEDICAL OFFICER OF HEALTH FOR BRIGHTON

IN Brighton, since October, 1931, scarlet fever patients have been isolated at home if they could be nursed in a room by themselves or in a room with their mother in a separate bed. After a period of four years I think it worth while recording the results, although even now the numbers are small.

TABLE I

*A Contrast in the Numbers of Secondary and Return Cases following Home and Hospital Isolation*

Intervals in days after isolation of patient	Secondary cases.								Return cases.	Total and per cent.
	6	7	8-14	15-21	22-28	29-35	36-42	42+		
Nursed at home (892 cases).	2	3	16	3	3	1	1	..	5	34 (4%)
Removed to hospital (725 cases).	..	..	3	2	1	1	..	..	34	41 (5.5%)

TABLE II

*Non-immune School Contacts with Onsets 6 days or more after Notification*

—	Secondary cases.	Return cases.	Total.	Percentage of contacts infected.
892 cases nursed at home in contact with 354 children of school age.	15	3	18	5.0
725 cases removed to hospital in contact with 515 children of school age.	2	25	27	5.1

As shown in Table I. the result of home isolation, particularly in the first fortnight, compares very badly with that obtained by the removal of the patient to hospital. On the other hand, under the hospital conditions stated later in the paper, it would seem that the greater infectivity of patients discharged from hospital, as shown by the number of return cases, outweighs the excess of infections from home-nursed cases during the period of isolation.

A better appreciation of the position as to infectivity is gained from Table II., which shows a greater number of school-children at risk per family in the hospital-nursed group and an equal percentage of family reinfection

in each group. From this Table it appears that in the age-group 5-14 the chances of infection are about equal, whether or not the patient is removed to hospital. An analysis of Table I. shows that equal percentages of mothers are infected whether or not the child is removed to hospital, which is remarkable seeing that the mother is usually the nurse of the child isolated at home. The figures are too small, however, to justify any definite conclusion.

To make home isolation more efficient is difficult as the health officer cannot control family life; on the other hand, it is possible to avoid cross-infection in hospital by such methods as cubicle isolation, open-air nursing, and a strict isolation of the individual patient by a highly trained nursing staff. Whether or not this is worth while to save a 5 per cent. reinfection-rate in a mild disease such as scarlet fever is worthy of consideration.

*Saving obtained by home nursing.*—In Brighton in the years 1922-25 the removal-rate was 74 per cent., whilst in the years 1932-35 the removal-rate was 45 per cent. This meant an actual reduction of the number of patients removed to hospital in the latter period of 472. The average stay in hospital being five weeks, this meant a saving of 2360 weeks of hospital treatment. As the diminution in the number of hospital-nursed cases allowed us to nurse our tuberculous joint and other orthopaedic cases in a vacated ward I estimate the saving at some £1000 a year. It may be objected that I have not taken into account the loss of school attendance by the prolonged exclusion of the contacts of home-nursed cases. In Brighton there is no such loss as the rules for exclusion of contacts is the same—namely, until the Monday week following isolation either at home or in hospital. I can trace no school or other infections from this short exclusion of contacts with home-nursed cases.

TABLE III

*Intervals between the Discharge of Hospital-nursed Cases and the Onset of Return Cases*

Weeks.				Months.			Total.
0-1	1-	2-	3-	1-	2-	3+	
8	7	5	2	10	2	0	34

*Infectivity of the hospital-nursed cases.*—The nursing of patients in Brighton is in large wards of 14 beds where uncomplicated cases after three weeks in bed mix freely with each other. The absence of cubicle nursing and the free contact of the patients who are

up and about no doubt leads to continuous cross-infection and probably accounts for the high infectivity of the patient on discharge, an infectivity which often lasts over a long period, as is shown by Table III., and by the occasional occurrence of cases at school after the return of the discharged case four clear weeks after discharge (not two weeks as is usual).

#### CONCLUSIONS

In cases in which the patient can have a bedroom to himself home isolation is justified: (a) by the non-exposure of the patient to cross-infections and his relatively low infectivity at the end of the isolation period: (b) by the large saving in the cost of hospital isolation of the patients and the use for other purposes of the increased hospital accommodation made available.

### THE DISTRICT MEDICAL SERVICE UNDER THE POOR LAW

#### I

A CONTINUITY of principle may be observed in English poor-law legislation. The Poor Law Act, 1930, requires the council of every county and county borough "to set to work all such persons as have no means of maintaining themselves," but also "to provide such relief as may be necessary for the lame, impotent, old, blind and such other persons as are poor and not able to work." This differentiation between able-bodied and non-able-bodied extends as far back as an Act of 1388 under which differing treatment was laid down for "beggars impotent to serve" and "those able to serve or labour." The distinction is repeated in an Act of Henry VIII. which has reference to "every aged, poor and impotent person" and "every sturdy vagabond." The Poor Law Act of Elizabeth provided for the raising of money by the overseers, inter alia, "for relief of the lame, impotent, old, blind and such other among them being poor and unable to work" almost the wording of the Act of 1930.

Throughout this period, and until later, the relief was in respect of destitution and not sickness, and the various Acts of Parliament, including that of 1834, did not specifically provide for medical relief. The poor-law commissioners, reporting in 1840, said:—

"Previously to the passing of the Poor Law Amendment Act there existed no statute expressly authorising the parish authorities to provide medical relief for the poor. In the statute of Elizabeth no allusion to such relief is to be found and in the subsequent Acts of Parliament relating to the poor the legislature has been entirely silent on the subject. In the absence of any positive provisions medical aid has nevertheless been supplied to the poor, and, as might have been expected from the uncontrolled discretion of the parish officers of 15,000 districts, the arrangements for the purpose have been almost infinitely various."

The commissioners who reported in 1834 on the Administration and Operation of the Laws of the Relief of the Poor made scanty reference to medical relief, remarking as regards outdoor relief: "On the whole, however, medical assistance seems in general to be adequately supplied and economically, if we consider only the price and amount of attendance." Thus, though there was an absence of direct statutory provision, medical relief had become by 1834 an established practice to a wide extent, and in certain districts medical assistance is said to have been given to practically "the whole mass of the labouring population," such assistance being given under contract of the overseers with a local surgeon.

The recognition of a poor-law medical service is indicated by the terms of the letter addressed to the recently constituted boards of guardians by the commissioners on Jan. 31st, 1837, which stated: "The consideration of the Guardians, on their first day of meeting, will be bestowed on the arrangement of the districts for the administration of medical relief, and the appointments of the medical officers." The introduction of the term "district medical officer," and the first obligatory requirement to appoint fit persons to such office, appears to date from the General Order (Consolidated) 1847, while security of tenure was granted under the Medical Appointments Order, 1857.

#### II

The conditions prevailing in the poor-law medical service a century ago gave rise to considerable dissatisfaction. The matter is discussed in the report from the Select Committee (1838) on the Poor Law Amendment Act and in the report of the poor-law commissioners on the Continuance of the Poor Law Commission (1840). For the former evidence was taken from a number of medical witnesses, medical officers engaged in poor-law duties and others as Dr. Kay and Sir Astley Cooper, and it is of interest to recall that evidence was given on behalf of the British Medical Association, then in its infancy, by Dr. Farr who was a member of the council. For the latter report evidence was obtained from the assistant commissioners throughout the country to whom a questionnaire was submitted and a detailed memorandum was also received from the British Medical Association.

Dissatisfaction arose from various sources—undue size of districts, inadequacy of remuneration, the method of appointment, insufficient qualification. In several unions the practice prevailed of submitting the appointment, which was a yearly contract, to competitive tender, and it might go to the lowest bidder: apart from inherent objection to this system it caused grave dissatisfaction to the profession by encouraging the introduction of rivals who accepted the contract at a low figure in order to obtain a footing in the district. On this point Sir Astley Cooper said: "If a medical man comes into the district and says 'I will attend for £50 where the resident practitioner has offered to attend for £100' there can be nothing more horrible or more degrading to the profession or more injurious to the poor." On qualifications there was dissatisfaction as officers might be, and were, appointed who possessed no surgical diploma. Remuneration was evidently a thorny problem: it was provided by salary, by payment per case, or by a combination of these methods which allowed a salary for those on a permanent list and a payment per case for others: Dr. Farr estimated the average remuneration to be about 3s. 3½d. per case in the provinces and it was stated to be 1s. 5d. in the metropolis. The question of medical extras aroused comment, especially in regard to the payment per case under which system there might be motive for increasing the number of cases by encouraging applications for medical relief through "recommending extra sustenance in the form of meat, ale and wine." Passing reference is made to whole-time appointments which appear to have been first instituted in Leighton Buzzard where a salaried officer, prohibited from private practice, attended exclusively on the poor, including the workhouse appointment: this appears to have been the solitary instance but it impressed the poor-law commissioners as definitely advantageous.

Interest attaches to the memorandum submitted by the British Medical Association as a matter of history and in view of some recent developments in the district medical service. Apart from other matters the Association recommended two alternative plans for remuneration. The first was by fixed salary adjusted to the average number of cases and the average number constantly on the sick list, density of population, &c., "the average charge for one person constantly on the sick list (or for attending 365 days of illness) should be about £5 5s. 0d., or for each case of illness 7s. 6d." The second plan is of special interest as suggesting in 1839 an open choice method for the poor-law population. The memorandum reads:

1st. Let a list be formed of all legally qualified practitioners in the district or Union who have been in practice a given time (from three to five years) and who have resided in the district at least one year, who are willing to attend the paupers if called upon.

2nd. Let annual or half-yearly tickets be given to all the poor on the pauper list, or to those not on the pauper list, whom the Guardians may consider proper objects for medical relief. Let these tickets bear a certain value, according to the locality, &c.; let the poor deposit their tickets with the medical practitioner whom they shall select for their attendant. The acceptance of the ticket would guarantee his attendance for the year, or half-year, as the case might be, and he would be paid the amount of his tickets quarterly.

3rd. Or, a salary being fixed, as the amount of remuneration for any district, it might be divided according to the number of tickets each medical man might hold.

In cases where the Guardians might find it necessary to give a ticket for attendance to a person actually sick, as in the instances of those not belonging to the parish, the ticket should bear a higher value.

It is acknowledged that there are several strong objections to the above plan; it would greatly lessen the value of parochial appointments, and it is feared that, in districts where there were many medical men, the responsibility, by being so much divided, would be also lessened. Any plan of medical superintendence could not be so effectually carried out, and the registers of the cases of disease would not be so carefully attended to; still the plan is worthy of a trial.

This is an example of history repeating itself.

The Select Committee did not make very definite recommendations regarding medical service beyond the following resolution:

"That the administration of medical relief to the poor has been in many respects amended under the new law, but that there is still room for further improvement; that the medical districts, in some instances, seem to be inconveniently large; that they should be of such a size as to admit an easy access of the medical man to his patients; and that the remuneration should be such as to insure proper attention and the best medicines."

The report of the poor-law commissioners recommended a fixed remuneration such as would afford a payment per case of 6s. or 6s. 6d. for those on a permanent list and not exceeding 10s. for those not on such list, it being emphasised, however, that in the second category medical relief might be granted by way of loan which would encourage recipients to make prior arrangements by means of sick-clubs or friendly societies.

While it is of interest and advantage to recall this former history it must be remembered that there is little true analogy with present-day conditions; infectious disease was rife, but there were no isolation hospitals; tuberculosis was rife, but there were no sanatoria; the voluntary hospital system was but imperfectly developed, and treatment was almost entirely domiciliary.

## THE SERVICES

### ROYAL NAVAL MEDICAL SERVICE

Surg. Lt.-Comdrs. J. G. Maguire to *Adventure*, and F. W. Besley to *Victory* for R.N. Hospl., Haslar.

Surg. Lts. G. A. Lawson to *President* for three months' course, and G. S. Thomas to *Ganges* and for Shotley Sick Quarters.

Sir Gilbert Blane Gold Medals have been awarded to Surg. Capt. D. H. C. Given, R.N., retired, and Surg. Comdr. M. B. Macleod, R.N., Assistant to the Director-General in the Medical Department.

### ARMY MEDICAL SERVICES

Col. J. H. Campbell, D.S.O., late R.A.M.C., having attained the age for retirement, is placed on ret. pay.

Lt.-Col. and Bt. Col. R. M. Dickson, O.B.E., from R.A.M.C., to be Col.

Col. Dickson joined the R.A.M.C. in 1908 and was an acting lieutenant-colonel in 1919. His stations have included Glasgow, Lucknow, Ferozepore, Lahore, London, and Ceylon, where he is senior medical officer. He was in France from 1914.

### ROYAL ARMY MEDICAL CORPS

Lt.-Cols. A. H. Bond and S. J. A. H. Walshe, D.S.O., having attained the age for retirement, are placed on ret. pay.

Majs. to be Lt.-Cols.: J. Walker, M.C., S. Arnott, and T. L. Fraser, O.B.E.

Maj. C. P. Chambers and Capts. D. C. McC. Ettles and R. R. Leaning were successful in the examination (in written subjects) of officers with a view to promotion in the R.A.M.C.

### SUPPLEMENTARY RESERVE OF OFFICERS

Lt. G. F. E. Ramsden to be Capt.

### ARMY DENTAL CORPS

The War Office announces that applications are invited from dental surgeons for appointment to six commissions in the Army Dental Corps. Candidates selected will be required to present themselves in London for interview and physical examination about the middle of July next. They must be registered under the Dentists Acts or Medical Acts, and be not over the age of 28. In the first instance short-service commissions are for six years, at the end of which they may either retire with a gratuity of £1000 or apply for permanent commissions. Full particulars and form of application may be obtained from the Director, Army Dental Service, War Office, S.W.

### TERRITORIAL ARMY

Capt. C. D. Bruce to be Maj.

Capt. G. Green resigns his commn.

### ROYAL AIR FORCE

Wing Comdr. G. H. H. Maxwell to R.A.F. Station, Manston, for duty as medical officer.

Flight Lt. P. H. Perkins is promoted to the rank of Squadron Leader.

### DEATHS IN THE SERVICES

Fleet Surgeon ROBERT FREDERICK YEO, R.N. ret'd., who died on June 15th at Alverstoke, Hants, qualified L.R.C.P.I. in 1875 from Trinity College, Dublin. In the following March he entered the Navy as surgeon and had risen to the rank of fleet surgeon in 1896. During operations in Egypt in 1882 he received the approbation of the Admiralty. Later he became surgeon of Malta Hospital.

Colonel JOHN POWELL, D.S.O., late R.A.M.C., who died on June 8th at Iffley, Oxford, in his 60th year, was the son of Mr. John Clarke Powell of Dublin. He was educated at Cambridge and Trinity College, Dublin, qualifying in 1899, and entering the R.A.M.C. in the following year. In September, 1909, he was attached to the Egyptian Army for seven years. From 1914-18 he served in Egypt and France, was thrice mentioned in dispatches, and awarded the D.S.O. and other distinctions. He was an all-round sportsman, proficient at tennis, swimming, and shooting.

## CORRESPONDENCE

## PRONTOSIL IN STREPTOCOCCAL INFECTIONS

To the Editor of THE LANCET

SIR,—In view of the promising results reported in THE LANCET of June 6th it is very desirable to complete our clinical trial of Prontosil treatment in streptococcus-infected cases as quickly as possible; and subsequently—if laboratory tests seem to warrant it—to undertake a similar thorough trial with the related substance *p*-aminobenzenesulphonamide in a similar large group of puerperal fever cases, in order that the experience gained with both agents may become generally available without delay.

To this end we would ask for the coöperation of private doctors, hospitals, and public health authorities in sending to us puerperal fever cases which are known to be, or likely to be, infected by hæmolytic streptococci. Needless to say we do not want old-standing cases of parametritis, white leg, &c., nor do we suggest the removal of moribund cases to hospital. Acute early cases seem likely to benefit most by the treatment. To secure admission it is only necessary to communicate with the resident medical officer by telephone (Riverside 6081/2), giving a few particulars of the case.

I am, Sir, yours faithfully,

LEONARD COLEBROOK.

Bernhard Baron Memorial Research Laboratories,  
Queen Charlotte's Hospital, W., June 12th.

## EARLY AMPUTATION FOR SEVERE INJURY

To the Editor of THE LANCET

SIR,—With reference to an annotation under this heading in your issue of May 30th (p. 1249), it was at a meeting attended by many members of the R.A.M.C. that Prof. A. K. Henry, head of the surgical unit at the Egyptian Faculty of Medicine, Cairo (Kasr-el-Ainy Hospital), formulated his preliminary ideas and results. Unfortunately, owing to a crowded programme, there was no time to prolong the discussion or emphasise the revolution these ideas should cause in the practice of advanced dressing stations, field ambulances, and first-line casualty clearing stations. Abdulsamie's paper gives a very clear description of the ideal treatment and I maintain that the case for "immediate" amputation is proved.

Your call for further observations is certainly well timed, and I hope that officers of the fighting services will be able to give their views and opinions. At the commencement of the last war I was with the French VIIIth Army and I was greatly hampered by the official attitude that an amputated patient was an expense to the State. I am happy to remember that with the British forces no consideration of future pensions was allowed to interfere with our practice; but with the vastly accelerated means of transport in late years I am afraid there may be a danger of trusting to rapid evacuation of severely wounded instead of immediate attention, that is "amputation," to the severe crushes in the first-line units.

I am, Sir, yours faithfully,

H. STIVEN,

Retd. Lieut.-Col., R.A.M.C.

Demerdache Hospital, Cairo, June 9th.

## THE PHANTASY OF MURDER

To the Editor of THE LANCET

SIR,—I understand that the murderer of a woman in a Clapham flat has had his appeal dismissed and as this matter is no longer sub judice it is permissible to draw attention to a fact that has long been

neglected. This man made a confession of having committed another murder three years ago, but was acquitted. This acting a phantasy of murder indicates the future murderer but it is treated by the judicial authorities with off-handedness.

This is by no means the first case in which a murderer has made a false confession and has had it disregarded by the police but has proceeded to commit a real murder. Some years ago a young man confessed to the police in Dartford that he had killed a boy. His confession was found to be false and he was discharged and told not to be so foolish. A few days later he took a knife and with it killed a girl on Dartford Heath. I have recently pointed out that this false confession of murder is an early symptom of schizophrenia (Clin. Jour., May, 1936), but there is little opportunity to confirm this belief. I would suggest, however, that the matter is proved sufficiently for all persons making false confessions of murder to be recommended by the judicial authorities for medical examination by a trained psychiatrist. If this is done some unfortunates may avoid being murdered and some schizophrenics avoid hanging.

I am, Sir, yours faithfully,

Harley-street, W., June 16th.

CLIFFORD ALLEN.

## AVITAMINOSES

To the Editor of THE LANCET

SIR,—In a recent paper<sup>1</sup> Loewenthal, working in Uganda on cases of vitamin-A deficiency, summarises the signs and symptoms which have so far been ascribed to this deficiency, and divides them into those which he accepts and those of which he is doubtful, as follows:—

## ACCEPTED

*Eye manifestations.*—Xerophthalmia; keratomalacia; night-blindness.

*Skin manifestations.*—Harsh dryness of the skin, with tendency to papular eruption. Nails lose lustre and become striated and brittle.

## DOUBTFUL

- |                             |                         |
|-----------------------------|-------------------------|
| 1. "Neuritis."              | 5. General infections.  |
| 2. "Sore mouth"; perlèche.  | 6. Cutaneous sepsis.    |
| 3. "Itchy" scrotum.         | 7. Changes in the hair. |
| 4. Diarrhoea and dysentery. |                         |

With regard to the first three of the "doubtful" group, a paper by Pallister and myself<sup>2</sup> proves fairly conclusively, if not absolutely, that they are due to a deficiency of the P-P (pellagra-preventive) factor; it is significant that Loewenthal states that it is now generally believed that perlèche is due partially to an attack by fungus on the mouth, while Pallister and I found similar evidence of fungus attacking the scrotal skin in some of our cases and that a fungicide such as Whitfield's ointment was of value in treatment. Fungus in these cases seems to me to play a similar part to that of sun exposure in pellagra, having an excessive effect on the skin of those people who have deficiency of the P-P factor in their food. The diarrhoea and dysentery so long associated with pellagra may well be, as far as my experience of a few cases of characteristic pellagra in Malaya goes, causative factors in producing pellagra rather than effects of pellagra. If these arguments can be confirmed, then pellagra throughout the world may be finally accepted as due to deficiency

<sup>1</sup>Loewenthal, L. J. A.: Ann. Trop. Med., 1935, xxix., 467.

<sup>2</sup>Landon, J. V., and Pallister, R. A.: Trans. Roy. Soc. Trop. Med. and Hyg., 1935, xxix., 121.

of the P-P factor, and the disease we have described in Malaya may be accepted in turn as pellagra. I have not in Malaya seen any evidence that Loewenthal's "doubtful signs," Nos. 5, 6, and 7, are due to deficiency either of vitamin A or the P-P factors specifically.

Whether the name vitamin B<sub>2</sub>, vitamin G, or P-P factor is used seems not to matter at present if one recognises that a chemical substance present in yeast, and present in many protein foods, which survives autoclaving, will cure these pellagrous conditions in their early stages, and that in all communities that subsist chiefly on carbohydrate food a reasonable amount of protein food containing the P-P factor is required to balance, possibly to detoxicate, the carbohydrate. The biochemists may wish to confine the term vitamin B<sub>2</sub> to a particular chemical in food necessary for the growth of rats, or to subdivide it, or may even wish to discard it altogether; it is for that reason that I have used the name P-P factor in this letter.

I may mention here the other chemical substance, stated to be present in autoclaved yeast, which was found somewhat successful by Lucy Wills<sup>3</sup> in treating tropical macrocytic anæmia; personally, I have not found yeast or Marmite alone very beneficial in tropical macrocytic anæmia in Malaya. I believe that the treatment of the many factors concerned in the causation of such anæmia, certainly including malnutrition, is essential. It is of significance that the involvement of the central nervous system which may occur in macrocytic anæmias closely resembles that seen in cases of deficiency of the P-P factor; and nutritional peripheral neuritis, or beri-beri, may prove to be a closely related nervous disease so that the vitamin-B complex may ultimately be united in a whole once more.

I am, Sir, yours faithfully,

J. V. LANDOR.

General Hospital, Singapore, May 21st.

#### COMPLETE TRANSPOSITION OF THE VISCERA

To the Editor of THE LANCET

SIR,—I am anxious to obtain information about this condition, which I believe to be inherited as a Mendelian recessive, and shall be much obliged if anyone who sees a case will send me the following data. Are the parents blood relations or not? If they are blood relations, are they first cousins, and, if not first cousins, what is their exact relationship? I should also like to know the number and sex of the normal brothers and sisters, the sex of the patient, whether the parents are normal, and whether there is a history of a previous case in the family.

I am, Sir, yours faithfully,

E. A. COCKAYNE.

91A, Harley-street, London, W., June 11th.

#### AN OLD MEDICAL BENEVOLENT SOCIETY

To the Editor of THE LANCET

SIR,—Every medical man and woman is in sympathy with the work of the Royal Medical Benevolent Fund which completes its centenary this year and is the senior medical charity in this country. I should like, if I may, to bring to the notice of your readers an even older benevolent medical society which is not a charity but a provident association, the members of which insure themselves against ever needing the help of the Royal

Fund. The Essex and Herts Benevolent Medical Society was instituted in 1786 and has the Marquess of Salisbury as president. It is available for medical men residing in the two contiguous counties and is intended primarily for the assistance of widows and orphans; if from sickness, infirmity, or other unavoidable misfortune a member becomes totally incapacitated he can petition the court of the district in which he resides, and such cases have been generously helped. It astonishes me how few medical residents in Essex and Hertfordshire have taken advantage of the comfort it must be to many of them to feel that if they are taken their widows and children will have such consideration—and for the trifling subscription of one guinea a year.

I am, Sir, yours faithfully,

F. L. NICHOLLS.

Fulbourn, near Cambridge, June 11th.

#### GASTRO-ENTEROSTOMY IN INFANCY: TWENTY YEARS AFTER

To the Editor of THE LANCET

SIR,—In 1918 notes were published<sup>1</sup> of a case of Gastro-enterostomy at six weeks for Pyloric Stenosis; the patient recovered, and a few days ago he called to see me, now a man in his twentieth year. I did not make any clinical examination, but he stated that he was in perfect health, and to all appearances this is true. He is 6 feet in height and weighs 13 stone. I suggested to him that he should have an X ray examination of the stomach, as I wondered whether the pylorus had resumed its function, or whether the stomach still emptied through the stoma made at operation. From the report of the radiologist, Dr. H. Franklyn, it seems that stomach contents still pass entirely through the stoma. Gastro-enterostomy, for congenital pyloric obstruction, has now been superseded by a simpler operation. It is probable that not many persons are alive who have grown up from infancy with this condition, and I thought it would be of interest to report the progress of this case after so many years.

I am, Sir, yours faithfully,

Bradford, June 15th.

T. JASON WOOD.

#### ZINC IONISATION FOR HAY-FEVER

To the Editor of THE LANCET

SIR,—I read with some surprise the report in the lay press of a new 99 per cent. cure for hay-fever by intranasal ionisation, emanating from one of the London centres of medical education. I have been using the treatment there referred to since 1925, described my method first in the *British Medical Journal* in June, 1931, and reported a further series of results in 91 cases in April, 1932, in the same place, bearing out my original hopeful prognosis. In March, 1935, in an article in the *Medical Press and Circular*, I pointed out that in 5 per cent. of cases successfully treated in one year, there was failure in the succeeding year. Much depended on the selection of cases and the varying intensity of the symptoms from year to year. In my own experience of 600 cases personally treated I can claim but 60 per cent. "relief"; and though this is of considerable value to the patient, it is only relief, not, except on the rarest occasion, a permanent cure.

I am, Sir, yours faithfully,

PHILIP FRANKLIN.

Weymouth-street, W., June 16th.

<sup>3</sup> Brit. Med. Jour., 1931, i., 1059.

<sup>1</sup> THE LANCET, 1918, i., 804.

## PARLIAMENTARY INTELLIGENCE

### THE MIDWIVES BILL IN COMMITTEE

ON June 11th the Midwives Bill was further considered by Standing Committee C. of the House of Commons.

#### Compensation

On Clause 5 (Compensation to midwives ceasing or required to cease practice) an amendment by Sir KINGSLEY WOOD extending the provision of the clause to midwives who during 1935 gave notice of intention to practise was agreed to.—The MINISTER further moved a series of amendments designed to deal with the question of compensation paid to a midwife by a local authority. As drafted, he said that the clause provided that compensation payable to a midwife should be calculated with reference to her net emoluments during her period of work in the area of the authority up to a maximum of three years. The amendments were designed to secure that the calculation should be on the basis of the midwife's average net emoluments during a period up to three years in whatever area she might have worked. In as much as the local authority to whom the midwife surrendered her certificate would pay her the whole of her compensation, arrangements would be made by which such local authority could recover the appropriate proportion of such compensation due from other local authorities in whose areas the midwife might be working at the time her certificate was surrendered.—The amendments were agreed to.

Captain ELLISTON moved an amendment, the object of which was to allow a midwife to select either a three-year or a five-year period as the basis for the payment of her compensation.—Mr. SHAKESPEARE thought they ought to trust local authorities to act in a reasonable spirit.—Sir F. FREMANTLE urged the Minister to approach this question sympathetically. There was a danger, he said, that if the elderly midwives could not be assured of adequate compensation they would be compelled to carry on their work.—Sir KINGSLEY WOOD promised to look into the matter before the report stage.

Mr. PETHERICK moved an amendment providing that if any midwife was aggrieved by the refusal of an authority to pay her compensation under the clause, or by the amount of the compensation paid, she might appeal to the Minister whose decision should be final, or alternatively to a county court in accordance with the rules of court.—Sir KINGSLEY WOOD said he hoped the committee would not allow an alternative appeal but would decide in favour either of the Minister or the county court.—This amendment was withdrawn.—Mr. LUNN then moved an amendment providing that the appeal should be to the Minister whose decision should be final, which was agreed to.

Mr. KEELING said in the Bill as drafted midwives who retired voluntarily, or were required to retire from practice, were referred to as having been "removed from the roll." He did not think that such a phrase, which was ordinarily used in connexion with punishment for misconduct, should be employed in this connexion. Secondly, he thought it was desirable that there should be a potential reserve of trained midwives which could be drawn on in case of emergency, and such a reserve might be found among the retired midwives.—Mr. SHAKESPEARE said the Government did not anticipate any danger of a shortage of midwives.—Sir F. FREMANTLE thought it was a pity during the experimental stage of the Act to make a final decision and remove all these women from the roll.—Sir KINGSLEY WOOD said that where compensation had been paid for loss of office, if the person compensated returned to work the compensation paid would have to be returned. He did not anticipate that in any large number of cases under this Bill compensation would be paid back.—

Captain ELLISTON said that it was unfair that these retired midwives should be shut out permanently from working in their profession. The midwives felt strongly on the subject.—The amendment was withdrawn.

On the question that Clause 5 stand part of the Bill,

Mr. BATEY urged the Minister to reconsider the question of the word "net" in the case of midwives' annual emoluments. He thought they should simply take a three years' average.—Mr. M. BEAUMONT said that the Minister could not drop the word "net" because it was in the financial resolution. If the word "net" were taken out it would impose a charge. The term "net" meant the takings with all possible outgoings removed.—Sir KINGSLEY WOOD said in putting the word "net" in the Bill he was carrying out the suggestion of the Joint Midwifery Council. He did not think any serious difficulty would arise. When the Bill had passed he would lay down the general lines on which the authorities should work under this clause.

#### Prohibition of Unqualified Persons

On Clause 6 Mr. BATEY moved an amendment to exclude from the clause the exemption given to nurses registered under the Nurses Registration Act, 1919. He knew women, he said, who had been acting most successfully as maternity nurses for the past 20 years, but they had not bothered to register under the 1919 Act. This clause would take away their living.—Mr. SHAKESPEARE said the suggestion went contrary to the opinion expressed both by the Departmental Committee and by the Joint Midwifery Council. Those bodies were unanimous in stating that one of the great causes of mischief in the nursing of women in childbirth was the practice which had grown up in certain parts of the country of employing absolutely unqualified women in attendance during the ten days of the confinement. Doctors did not like the system, but it had never been found possible to abolish it. This clause was vital to the Bill. What it said was that no unqualified woman should attend a woman as a maternity nurse. As to exemption under the Nurses Registration Act he thought sufficient time had elapsed for the list to be fairly comprehensive.—Sir F. FREMANTLE said they had to recognise that there were not enough trained midwives to go round, especially in the more scattered areas of the country. It was therefore essential to allow the latitude given under this clause to registered nurses.—The amendment was rejected.

Mr. SHAKESPEARE said the intention of the clause was that a doctor should be able to employ nurses with general qualifications, and therefore he moved an amendment to limit the exemption under the clause to those nurses appearing on the general part of the Nursing Register. He also moved a consequential amendment dealing with the special case of institutions run by local authorities or others, and under this amendment discretion would be left to the medical officers in charge of the particular institution. The institutions affected by the amendment comprised any nursing home registered under the Nursing Homes Registration Act, 1927, or exempt from the operation of that Act under Section 6 thereof.—The amendments were agreed to and Clause 6 as amended was ordered to stand part of the Bill.

On the Second Schedule, Mr. SHAKESPEARE moved an amendment to enable a midwife who was practising in two or three areas to surrender her certificate to one local authority who would pay her compensation, and then the other authorities would make proportionate contributions according to the amount of work which the midwife had done in their respective areas.—The amendment was agreed to.

The committee stage being concluded the Bill as amended was ordered to be reported to the House.

## NOTES ON CURRENT TOPICS

## Importation of Scientific Apparatus

In the House of Commons on June 10th on Clause 8 of the Finance Bill Mr. MACLAREN moved an amendment to take away from the Import Duties Advisory Committee the discretionary powers as to the admission into this country of goods intended to be used in scientific research or for the purpose of advancing any branch of learning or art. The amendment, he said, was consistent with the idea of the clause which laid down that the exempted goods were not intended to be sold. These articles were not imported to compete against the production of anybody else. They were for the advancement of the intelligence of the community and therefore there should be no discretionary power left to any advisory committee.—Mr. SILVERMAN in supporting the amendment cited the case of a refugee with a German medical qualification, who was prevented under the existing régime in his own country from pursuing his professional activities there. He was allowed to come here with a temporary visa which, unless it was extended, would expire next week. When he entered this country six months ago he brought with him certain instruments about which he was quite properly challenged by the Customs authorities. He asked if he had to pay duty on them, and was told that he could bring them in provided he deposited a sufficient amount to cover the eventual duty if it was to be levied. He agreed to do so and deposited £150. That was six months ago, but the authorities had not yet made up their minds whether duty was leviable or not.—Mr. CHAMBERLAIN, Chancellor of the Exchequer, said that the effect of the amendment would be that an importer having established to the satisfaction of the Advisory Committee that he had fulfilled the two conditions under the clause would at once be able to demand the right of importation of these articles free of duty. That would be inconsistent with the provisions of the Import Duties Act and the duties which were laid upon the Advisory Committee in considering any application made to them. If the amendment were carried many articles which would fulfil the two conditions could be imported free of duty, although they could equally well be made at home. That would be contrary to the spirit of the Act.—Mr. A. BEVAN said that in this very special market it surely should be possible for people to buy scientific instruments where they wished. It was not desirable that they should hand over a monopoly for the making of scientific instruments to anyone in this country. It was a good thing that the makers of instruments here should have to compete with manufacturers in other parts of the world in order that our own scientific progress might be kept abreast of the rest of the world.—Mr. BENSON said that in the case of certain drugs, particularly organic drugs, the products of two firms might so far as could be ascertained be identical in quality, yet it might be known that they had quite different physical and theoretical effects. If an experimenter in this country decided that he wanted to experiment with a German drug, or if he felt that the German drug gave a better result, he would go to the Advisory Committee and ask for permission to import, explaining that the drug was for purely scientific investigation, and then under the second part of their instructions they would have to decide whether the importation was expedient. It was ridiculous to suggest that the Advisory Committee were capable of coming to a decision on matters of scientific experiment with the accuracy and precision that an experimenter could exercise.—After further debate the amendment was negatived by 217 votes to 135.

## River Pollution and Public Health

In the House of Lords on June 11th Lord GAINFORD moved the second reading of the Public Health (Drainage of Trade Premises) Bill. He said that the

principle of the Bill was to improve the purity of the streams and rivers of this country. It was based on the recommendations of a Joint Advisory Committee appointed in 1930 by the Ministry of Health. That committee recommended, first of all, that the local sanitary authorities in the country should take and dispose of trade effluents. They also recommended that traders should have a right to discharge their effluents into the sewers of the local sanitary authorities; that there should be regulations for the preliminary treatment of these effluents where necessary; that they should provide separate sewers, if necessary; and that the local sanitary authorities should have the right of access to traders' premises in order to inspect the effluents in regard to the poisonous matters which might have to be taken into their sewers. Further, they recommended that certain poisonous effluents should be excluded; that riparian interests should be protected, and that the Ministry of Health should have power to interfere where it was thought necessary in the interests of various authorities. Those recommendations had practically all been accepted in the provisions of this Bill. Examination of the recommendations had been made by a great number of parties interested in the purity of our rivers, including the Society of Medical Officers of Health, and all of the bodies consulted had agreed to them. The Ministry of Health had been consulted also as well as the Ministry of Agriculture and Fisheries, the Federation of British Industries, the County Councils Association, the Urban and Rural District Councils Association, and the Association of Municipal Corporations. He hoped that before the committee stage there might also be consultations with the London County Council and the Standing Joint Committee of the Metropolitan Borough Councils so that they might have their support in addition to that of the other bodies he had mentioned. By the passage into law of this Bill they would do something to improve the condition of the water-supply as well as to improve amenities.

Lord RITCHIE OF DUNDEE said he was afraid if this Bill passed unamended it would not have the effect desired. He was speaking on behalf of the dock and harbour authorities, many of whom were vitally concerned with questions relating to the purification of their waters and with obstructions caused to navigation through sewage effluents falling into those waters. The Port of London Authority had been gravely concerned for years at the condition of the water in the Thames. The difficulties which were very great would be increased under this Bill.—Lord MELCHETT said he thought that the measure was designed to improve existing conditions, and he hoped that it would receive a second reading.—The Earl of LISTOWEL said the London County Council was as anxious as anyone else to preserve the purity of streams and tidal waters, and welcomed the principle embodied in the Bill.—Viscount GAGE said the Government's attitude towards the Bill was one of sympathy, and they were glad to see the degree of unanimity which had been reached. Some further safeguards might be necessary on the committee stage.

The Bill was read a second time.

## QUESTION TIME

WEDNESDAY, JUNE 10TH

## Fire Prevention in Hospitals and Institutions

Mr. KELLY asked the Minister of Health whether recommendations had been made to hospitals and other institutions as to the prevention of and protection from fire; and whether any committee of experts had been appointed to deal with these dangers.—Mr. SHAKESPEARE, Parliamentary Secretary to the Ministry of Health, replied: No general recommendations have been issued by my Department, but attention is drawn to the importance of this matter when plans of buildings are being considered, or otherwise as occasion arises. My right hon. friend is not aware that any committee of

experts has been appointed to deal with safeguards against fires at institutions.

Mr. KELLY asked the President of the Board of Education whether he had received reports as to school buildings and their protection from fire; and what steps had been taken to issue recommendations on fire prevention to all schools, public and private.—Mr. OLIVER STANLEY replied: If in the course of inspection H.M. inspectors find that the safeguards against fire are inadequate the attention of the school authorities is called to the matter. The Home Office handbook, "Fire Precautions in Schools," has been brought to the notice of local education authorities and the governors and managers of schools recognised by the Board in the Board's Circular 1446, dated Jan. 20th, 1936.

#### Motor Driving Tests

Mr. McENTEE asked the Minister of Transport the number of men and women examined for the driving test up to the last available date; and the number that had failed.—Mr. HORE-BELISHA replied: Up to and including May 30th, 316,886 persons have been examined, of whom 57,594 failed to satisfy the examiners. From May 6th, 1935, since when separate records for men and women have been kept, to May 30th, 1936, the figures are:

Men examined	.. 234,827	Failed	.. 41,083 (17.4%)
Women "	.. 55,248	"	.. 14,094 (25.5%)

#### Wheat Reserve for War Emergency

Mr. LIDDALL asked the Minister for the Co-ordination of Defence what steps had been taken to build up in this country a reserve of wheat sufficiently large to meet any contingencies likely to arise in the event of war.—Sir T. INSKIP replied: The question of a sufficient wheat reserve will be considered by the committee which is now engaged in examining the whole subject of food supplies in time of war. At the present time, including the balance of the home crop, the wheat in public granaries and millers' stores, and flour in the hands of millers, bakers, and retailers, the effective stock of wheat and flour in this country is understood to be about equal to three months' consumption. This figure does not include wheat normally on passage, which might amount to a further month's consumption.

THURSDAY, JUNE 11TH

#### Surveys of Overcrowded Housing Conditions

Mr. GRAHAM WHITE asked the Minister of Health if the survey of overcrowded conditions, as defined by the Housing Act, 1935, had been completed; and if he could give some indication of the number of houses overcrowded and the number of persons concerned.—Sir KINGSLEY WOOD replied: Up to June 1st 1024 local authorities had submitted reports. The reports show that 6,431,464 houses were inspected, of which 247,884 were found to be overcrowded. These reports include 55 county boroughs, in which 1,902,149 houses were inspected and 71,600 were found to be overcrowded. Up to June 10th reports have been received from 1272 local authorities out of a total of 1536. These reports show that 7,893,399 houses were inspected, and 296,738 were found to be overcrowded, an average of 3.8 per cent. The reports received include most of the large centres of population and I do not think that the results are likely to be substantially affected when the outstanding reports which I have urged local authorities to submit forthwith are received.

#### Health Visitors and the Pre-School Child

Mr. JOEL asked the Minister of Health whether it was his intention that, in connexion with the visiting by health visitors of all children under the age of five who did not attend school, such visitation would affect all classes of the community; and, if not, how the scope of such visits would be limited.—Sir KINGSLEY WOOD replied: I have recently issued a circular on this subject. The question of visiting in any particular case is one within the discretion of the local authority, who will naturally take account of the extent to which to their knowledge the health of the child is already supervised.

#### Destruction of Human Food

Mr. WILSON asked the Minister of Health the cases brought to his notice in which, during the last 12 months,

food of any description fit for human consumption had been destroyed and, in each case, the reason for the destruction and the action taken by the department, either before the destruction or since; and whether it was intended to take further powers to prevent such destruction.—Sir KINGSLEY WOOD replied: No such cases have been brought to my notice as having occurred in England or Wales, and I do not consider that it is necessary to take steps to obtain further powers in the matter.

#### Midwifery Bill for Scotland

Mr. LEONARD asked the Secretary of State for Scotland if he proposed to present to Parliament a Midwifery Bill for Scotland; and, if so, when he would introduce it.—Lieut.-Colonel COLVILLE, Under-Secretary of State for Scotland, replied: Yes, Sir. It is the intention of my right hon. friend to introduce a Bill this session, but he is not yet able to announce a definite date. As the hon. Member is aware, the Scottish problem differs both in nature and extent from that in England, and in framing proposals my right hon. friend has thought it expedient to secure the fullest measure of agreement with local authorities and other interests concerned. Consultations to that end are actively proceeding.

#### Committee on Scottish Health Services

Mr. LEONARD asked the Secretary of State for Scotland when the report of the Committee on Scottish Health Services would be available.—Lieut.-Colonel COLVILLE replied: I understand that the report of the Committee on Scottish Health Services will probably be submitted to my right hon. friend by the end of this month. Publication will follow immediately the report is received.

MONDAY, JUNE 15TH

#### Destruction of Human Food

Mr. WILSON asked the Minister of Agriculture if he would state the cases brought to his notice in which, during the last 12 months, food of any description fit for human consumption had been destroyed, and in each case the reason for the destruction and the action taken by the department either before the destruction or since; and whether it was intended to take further powers to prevent such destruction.—Mr. ELLIOT replied: The only such cases that have been brought to my notice relate to certain heavy landings of highly perishable fish which the port markets were unable to absorb. The quantities of fish thrown back into the sea were about 4 or 5 tons of pilchards in November of last year, and about 60 tons of herrings in August and September of last year and in May of this year. The absence of the Italian market was mainly responsible for the destruction of the pilchards. As regards the steps which might be taken to deal with occasional landings of herrings surplus to the capacity of the markets, I would refer the hon. Member to the answer I gave on June 11th. As these cases occur only very exceptionally, the quantities involved in those I have mentioned amounting to not more than 0.01 per cent. of the landings of wet fish by British fishing vessels in England and Wales for the last 12 months, I do not think it would be possible to provide against them by legislation.

#### Physique of Recruits for Defence Services

Mr. EMMOTT asked the Prime Minister what percentage of the applicants to the recruiting offices last year were refused on the grounds that they were not physically fit; and what steps the Government proposed to take to raise the present level of the physique of the nation.—Mr. BALDWIN replied: The percentage for England, Scotland, and Wales is approximately 35. As regards the last part of the question, I would refer my hon. friend to Circular 1445 issued by the Board of Education in January last, from which he will see that in addition to giving close attention to the various health services, such as the School Medical Service and the Maternal and Child Welfare Service, it is the Government's policy to promote the development of physical education for children of school age and for persons no longer attending school.

Viscountess ASTOR asked the Prime Minister to bear in mind that children who attended nursery schools were

5 lb. heavier and were taller than other pupils entering the elementary schools, and that the latter were physically defective; and that the only way to put this right was through a proper system of open-air nursery schools.

Mr. JOHNSTON asked if the right hon. gentleman was aware that in addition to the 35 per cent. of recruits rejected as physically unfit, another 30 per cent. were rejected later as medically unfit. As there was genuine agreement on all sides of the House that something ought to be done to improve the nutrition of the people, would the Prime Minister provide an opportunity for discussing the matter?

Mr. BALDWIN said that if the question was raised it would be discussed. This was a matter which the Government now had in hand.

#### Nutritive Values of Foods

Mr. LENNOX-BOYD asked the Minister of Health whether he had any statement to make on the fact, quantitative and qualitative, in relation to the diet of the people, or any proposals to effect changes therein which might appear desirable in the light of modern advances in the knowledge of nutrition.—Mr. SHAKESPEARE, Parliamentary Secretary to the Ministry of Health, replied: These questions have been referred to the Advisory Committee on Nutrition. As regards the facts the committee have reported that the available data are insufficient and have recommended the collection of further particulars. The committee have, however, recently stressed the importance of milk as a food.

Mr. SANDYS asked the Minister of Health the present average daily consumption per head of milk; and, in view of the conclusions of the recent report of the Advisory Committee on Nutrition, what steps he proposed to take further to increase it.—Mr. SHAKESPEARE replied: The present daily consumption of liquid milk in this country is estimated at slightly less than half a pint per head. The Government accept the views expressed by the advisory committee as to the high value of milk as a food, and schemes for the provision of milk, either free or at

cheap rates, to mothers and children are now in operation. The Government will give consideration to the further development of these schemes, but this must await the general review of milk policy which will take place when the report of the Milk Reorganisation Commission is available.

Replying to Miss Horsbrugh, Mr. Shakespeare said that he fancied it was the fact that the half-pint per head included the milk supplied in schools.

TUESDAY, JUNE 16TH

#### Dietaries in Scottish Prisons

Mr. JOHNSTON asked the Secretary of State for Scotland whether he would give for each of the five rates of dietaries in use in Scottish prisons the approximate cost of the food supplied to the prisoners per day; and what steps, if any, he proposed to take to ensure that the law-abiding working classes should be at least as well fed as the inmates of prisons, whose diet was prescribed by the regulations approved in June, 1931, and amended in August, 1932, and March, 1933.—Sir GODFREY COLLINS replied: The approximate wholesale cost of the ingredients of the items in the Dietary Rates per person per day in 1935 is as follows:—

Rate I.	.. ..	4½d.	Rate IV.	.. ..	6½d.
" II.	.. ..	5d.	" V.	.. ..	8½d.
" III.	.. ..	5½d.			

The costs would, of course, be higher if the ingredients had to be purchased at retail prices. In view of these figures I am unable to accept the suggestion made in the last part of the question.

Mr. JOHNSTON asked if the right hon. gentleman had not been assured by his medical advisers in charge of these prisons that the prison population were better fed after a period in prison than they were when they entered.

Sir G. COLLINS said that not only was the dietary better, but the regular life they led and the work they did had some bearing on this point.

## MEDICAL NEWS

### University of Cambridge

The general board propose to establish a post of assistant director of research in medicine. The holder will work at Addenbrooke's Hospital and the laboratories of the university under the direction of the regius professor of physic. If the appointment is made it will be for an initial period of three years at £700 a year.

On June 12th the following degrees were conferred:—

M.D.—Charles Hill.

M.B., B.Chir.—H. F. Anderson, D. N. Matthews, and J. D. M. Jones

M.B.—C. A. Dowling.

B.Chir.—E. M. Darmady.

### Royal College of Surgeons of England

A meeting of the council was held on June 11th, with Sir Cuthbert Wallace, the president, in the chair. Prof. Einar Key, of Stockholm, was admitted an hon. fellow of the College, and the honorary college medal was presented to Dr. J. A. Murray, F.R.S. Mr. R. M. Vick was re-elected to the court of examiners, Mr. W. Sampson Handley was reappointed as representative of the College on the court of governors of the University of Sheffield, and Dr. John Beattie was appointed as representative on the British National Human Heredity Committee. The Hallett prize was awarded to Kenneth William Starr of the University of Sydney, and the Sir Gilbert Blane medals to Surgeon Captain D. H. C. Given and to Surgeon Commander M. B. Macleod.

Diplomas of fellowship were granted to the following:—

A. S. Wesson, M.R.C.P. Lond., Univ. Coll.; D. C. Price, M.B. Lond., St. Bart.'s; Jean M. Dollar, M.B. Lond., Royal Free; G. S. Seed, M.B. Leeds, St. Bart.'s and Guy's; N. S. I. Narasimhan, L.R.C.P. Lond., Madras and Guy's; A. G. Williams, M.B. Wales, St. Bart.'s; E. R. G. Passe, L.R.C.P. Lond., St. Thomas's; R. H. Young, M.B. Camb., St. Thomas's; C. F. Evans, L.R.C.P. Lond., Melb. and Edin.; K. H. C. Hester, M.B. Lond., Guy's; L. W. Lauste, M.B. Lond., St. Thomas's; A. L. Kenyon, M.B. Manch.; O. J. Vaughan-Jackson, B.M. Oxon., London; J. R. Blackburne, M.B. Lond., St. Bart.'s; G. H. C. Ovens, M.B. Lond., St. Mary's; W. M. Capper, M.B. Lond., St. Bart.'s; Alan Bowen-Davies, M.B. Camb., Guy's;

A. G. Cross, M.B. Camb., St. Mary's and London; Bodo Schlenburg, M.B. Cape Town, St. Thomas's and St. Bart.'s; Ralph Shackman, M.B. Lond., St. Bart.'s and Sheffield; S. A. Mian, M.B. Punjab, London; R. L. Benison, M.B. Camb., St. Bart.'s; A. E. De Sa, M.B. Bombay, Univ. Coll.; J. D. Fergusson, M.B. Camb., St. Thomas's; F. I. Evans, L.R.C.P. Lond., Camb. and Guy's; S. Y. Feggetter, M.B. Durh.; G. N. Sen, M.B. Calcutta, St. Bart.'s; S. M. Thompson, L.R.C.P. Lond., Leeds; J. G. Bonnin, M.B. Melb.; T. M. d'O'Fay, M.B. Edin., Sheffield; F. G. Fenton, M.B. Melb., Guy's; R. W. S. Fox, M.B. Melb., Guy's; C. H. W. Lawes, M.B. Sydney, St. Bart.'s; Ruby G. Sharp, M.B. Cape Town, Guy's; Jacob Sherne, M.B. Leeds, Guy's; W. H. M. Smith, M.B. Edin., Liverp.; K. W. Starr, M.B. Sydney; J. C. Stewart, M.B. Melb., London; R. R. S. Strang, M.B. Glasg., Univ. Coll.; and Gerald Townsley, M.D. Belf., Univ. Coll.

Diplomas of membership were granted to Gordon Williams and Walter L. Isaac, of St. Mary's Hospital, and diplomas in anaesthetics were granted jointly with the Royal College of Physicians to the following:—

R. A. Beaver, Donald Blatchley, Henry Canwarden, J. A. Carman, Bernard Coden, Phyllis F. L. Daplyn, C. J. M. Dawkins, M. M. Deane, Margaret L. A. Galbraith, Harry Grant-Whyte, V. A. Goldman, G. G. Havers, M. W. P. Hudson, I. C. James, I. D. Jones, R. N. Jones, Agnes W. O. Kennedy, F. B. Mallinson, Ruth E. Mansfield, P. J. Nagle, P. M. Overton, C. B. Picken, R. A. C. Rice, A. D. Woolf, and Tamsin M. Wynter.

The following examiners were elected for the ensuing year:—

**Dental Surgery.**—Surgical Section: Mr. C. E. Shattock, Mr. E. G. Slesinger, Mr. C. P. G. Wakeley, Mr. Reginald Vick, Mr. P. H. Mitchiner, and Mr. Basil Hume. Medical Section: Dr. R. A. Rowlands, Dr. R. A. Hickling, Dr. A. H. Douthwaite, and Dr. Ernest Bulmer.

**Primary Fellowship.**—Anatomy: Mr. P. N. B. Odgers, Prof. H. H. Woollard, and Prof. R. B. Green. Physiology: Dr. D. H. de Souza, Prof. Hamilton Hartridge, Prof. Samson Wright, and Prof. John Mellanby.

**Diplomas of L.R.C.P., M.R.C.S.—Elementary Biology:** Mr. A. J. Grove, Mr. A. E. Ellis, Mr. W. A. Cunningham, and Mr. S. R. B. Pask. **Anatomy:** Mr. E. P. Stibbe, Prof. Lambert C. Rogers, and Dr. A. J. E. Cave. **Physiology:** Prof. A. S. G. J. McC. Huggett and Prof. Samson Wright. **Midwifery:** Mr. A. C. Palmer, Mr. Victor Lack, Dr. Malcolm Donaldson, and Mr. Trevor Davies. **Pathology:** Prof. James McIntosh, Dr. W. G. Barnard, Mr. Robert Davies-Colley, and Mr. B. W. Williams.

**Diploma in Public Health.**—Part I.: Prof. C. C. Okell. Part II.: Dr. James Fenton.  
**Diploma in Tropical Medicine and Hygiene.**—Major-General W. P. MacArthur and Dr. Hamilton Fairley.  
**Diploma in Ophthalmic Medicine and Surgery.**—Part I.: Mr. Leighton Davies and Mr. Affleck Greeves. Part II.: Mr. Foster Moore.

**Diploma in Psychological Medicine.**—Dr. F. L. Golla.  
**Diploma in Laryngology and Otology.**—Part I.: Mr. E. Musgrave Woodman and Mr. Sydney Scott. Part II.: Mr. T. B. Layton.

**Diploma in Medical Radiology.**—Part I.: Prof. J. M. Woodburn Morison. Part II.: Dr. Douglas Webster.  
**Diploma in Anaesthetics.**—Dr. H. E. Gaskin Boyle.  
**Diploma in Child Health.**—Dr. A. G. Maitland-Jones.

The posts of resident medical officer and house surgeon at the General Infirmary, Salisbury, were approved for recognition for the six months' surgical practice required of candidates for the final examination for the fellowship.

#### University of Oxford

Dr. H. A. B. Whitelocke and Dr. Arthur MacNalty have been elected to the board of the faculty of medicine by the general medical electorate.

#### University of Bristol

At recent examinations the following candidates were successful:—

##### FINAL EXAMINATION FOR M.B., CH.B.

**Section II.**—Senta Alkan, Bruno Isserlin (with distinction in surgery and obstetrics), J. S. W. Little, and Ernst Philipp.  
**Group I.**—Ursula G. Hewitt (with distinction in obstetrics).

##### FINAL EXAMINATION FOR L.D.S.

J. G. Coates, R. A. Hilton, Thomas John, C. L. Read, and A. J. Staple.

#### Medical Art Society

The private view of the second annual exhibition of this society will be held at 1, Wimpole-street, London, W., on July 1st from 2-6 p.m. The exhibition will be open during the same hours (except on Saturdays) until July 14th.

#### National Institute for the Deaf

In opening the new headquarters of the institute at 105, Gower-street, W.C., on June 11th, the Duke of York was able to announce that the Pilgrim Trust had promised £2000 to the jubilee appeal fund. The money is to be used to reduce the debt on the new buildings.

#### North Kensington Women's Welfare Centre

On Thursday, June 25th, at 8.30 p.m., at the centre (12, Telford-road, W.), Dr. Mary Redding will give a lecture demonstration on the theory and practice of contraception. Applications for tickets should be made to the secretary of the centre in advance. The lecture is open only to practitioners and medical students.

#### University College Hospital

A Bilton Pollard fellowship of an annual value of £650 has been founded for men students who have held a resident appointment at this hospital. Candidates must be members of the Royal College of Physicians of London or fellows of the Royal College of Surgeons of England and must declare their intention of practising in medicine or surgery. Applications should be sent to the secretary of the hospital not later than June 25th.

#### Fellowship of Medicine and Post-Graduate Medical Association

The following week-end courses have been arranged for July: children's diseases at the Princess Elizabeth of York Hospital (4th and 5th); heart and lung diseases at the Victoria Park Hospital (11th and 12th). An all-day course in proctology will be given at St. Mark's Hospital from the 6th to the 11th, and afternoon courses will be held in dermatology at the Blackfriars Skin Hospital (13th to 25th), and in urology at the All Saints' Hospital (July 13th to August 1st). On Monday, June 29th, at the Royal Westminster Ophthalmic Hospital, Mr. G. G. Penman will give a demonstration on fundi of medical interest at 4.45 p.m., and on Wednesday, July 1st, Mr. C. L. Gimblett will lecture on some points in medical ophthalmology at 5 p.m. On Tuesday, July 7th, at 8.30 p.m., at the in-patient department of the West End Hospital for Nervous Diseases, Mr. Lindsay Rea will give a demonstration on fundus oculi. Further information may be had from the secretary of the fellowship at 1, Wimpole-street, W.

#### Royal College of Surgeons in Ireland

Mr. Adams Andrew McConnell has been elected president, and Mr. William Doolin vice-president of the College. Mr. McConnell is a graduate of Dublin University and is senior surgeon to the Richmond Hospital; he specialises in the surgery of the brain and nervous system. Mr. Doolin is a graduate of the National University and is surgeon to St. Vincent's Hospital and to the Children's Hospital, Temple-street, Dublin.

#### British Postgraduate Medical School

On July 9th, 13th, and 16th, at 3.30 p.m., Mr. V. B. Green-Armytage will lecture at this school on gynaecology and midwifery in the tropics. Applications for tickets should be sent to the dean of the school, Ducane-road, London, W.12.

#### Handicrafts of the London Tuberculosis Dispensaries

An exhibition and sale of handicrafts made by the students attending classes at tuberculosis dispensaries in London will be held at the Carpenters' Hall, Throgmorton-avenue, E.C., on Wednesday and Thursday, June 24th and 25th. The hon. secretary is Mrs. William Brand, 8, Christ Church-place, Epsom, Surrey.

#### King's College Hospital

The Duchess of York, accompanied by the Duke, will open the completion of the nurses' home at this hospital on Nov. 4th, and will receive purses towards its cost which, including equipment, will amount to £30,000.

Lord Hambleden has been elected chairman of the committee of management of this hospital in succession to the late Earl Beatty.

#### Exhibition of Inventions

The twelfth International Exhibition of Inventions arranged by the Institute of Patentees will be held in the Central Hall, Westminster, from Sept. 30th to Oct. 10th, and the Northern Exhibition of Inventions in the St. George's Drill Hall, Newcastle-upon-Tyne, from Nov. 25th to Dec. 5th.

#### Royal Medico-Psychological Association

The ninety-fifth annual meeting of this association will be held from July 1st to 3rd at Folkestone under the presidency of Dr. M. Abdy Collins, who will give an address on the law and the present position of psychiatry. The second day of the meeting will be devoted to a discussion of the manic-depressive psychoses, at which papers will be read by Dr. A. J. Lewis, Dr. H. Tómasson, Dr. T. J. Hennelly, Dr. E. T. O. Slater, and Dr. A. Glen Duncan. At the last session Dr. F. L. Golla, Prof. W. Mayer-Gross, and Dr. Arthur Guirldham will read short papers. The secretary of the association is Dr. Reginald Worth, Springfield Mental Hospital, Tooting, London, S.W.17.

#### Botanical Therapeutics

In the course of a Chadwick lecture on plant pharmacology and medical practice, delivered in the Chelsea Physic Garden on June 11th, Sir William Willcox said that plant products rarely act as tissue poisons. For example quinine, which contains a quinoline nucleus and therefore might well be toxic to the liver, had no toxic effects when carefully used. In the chemical laboratory conditions were very different, and many of the modern artificially synthesised drugs proved to be liver and tissue poisons. At the same time it must be remembered that some of the most powerful therapeutic substances and poisons—e.g., aconitine, strychnine, quinine, hyoscyne, morphine, and cocaine—are derived from plants. Sir William strongly advocated a smaller dosage of morphine and its derivatives: in many conditions, including renal and hepatic disorders, doses of gr. 1/30 were better than those within the official limits (gr.  $\frac{1}{4}$ – $\frac{1}{2}$ ). More careful adjustment of dosage would give better results and involve less risk of addiction. Hyoscyne, too, could often be used more effectively and more safely in smaller quantities, such as gr. 1/400 instead of the ordinary gr. 1/200–1/100. On the other hand some plant products should sometimes be given more freely than is usual—e.g., digitalis in auricular fibrillation and sodium salicylate in acute rheumatism.

**St. Mark's Hospital, London**

On June 11th Lord Harewood laid the foundation-stone of the nurses' home at this hospital which is to be the first stage of a big reconstruction scheme. The home is to accommodate 50 nurses and 27 maids, and it is afterwards proposed to increase the number of beds in the hospital to 95, to provide a second operating theatre, and to enlarge the cancer research laboratories and the out-patients' and X ray departments. Approximately £40,000 is still needed to complete the work.

**Rehabilitation of Persons Injured by Accidents**

The Home Secretary, the Minister of Health, and the Secretary of State for Scotland have appointed Dr. J. F. E. Prideaux, an assistant director of medical services at the Ministry of Pensions, to be a member of the Inter-departmental Committee appointed last April to inquire into the arrangements made in this country for the restoration of the working capacity of persons injured by accidents.

**Worthing Hospital**

Work has been begun at this hospital on the erection of a maternity home at a cost of £13,840, and the contract has been signed for the building of a children's ward. The governors are considering the adoption of the federated superannuation scheme for nurses and hospital officers. Mrs. Arthur Lloyd, of Washington, has promised to give the hospital a deep X ray therapy apparatus. There is an excess of expenditure over income of £4206, and though Worthing has now a population of nearly 60,000, regular subscribers to the hospital number only 600.

**Vacancies**

For further information refer to the advertisement columns

*All Saints' Hospital for Genito-urinary Diseases, Austral-street, West-square, S.E.*—Hon. Pathologist.  
*Ashton-under-Lyne District Infirmary.*—H.S., at rate of £150.  
*Bedford County Hospital.*—First H.S., at rate of £155.  
*Birmingham and Midland Eye Hospital.*—H.S., at rate of £130.  
*Birmingham City, P.H. Dept.*—Two Res. Asst. M.O.'s, each £400.  
*Birmingham, Ear and Throat Hospital.*—Second and Third H.S., each at rate of £150.  
*Birmingham Selly Oak Hospital.*—Res. Surgeon, £700. Pathologist, £750. Also Radiologist, £800.  
*Blackburn County Borough.*—Asst. Dentist, £450.  
*Blackburn Royal Infirmary.*—Res. H.P., £175.  
*Bolton Royal Infirmary.*—H.S., £125.  
*Bradford New Royal Infirmary.*—Two H.S.'s, each £135.  
*Brecon County.*—Asst. M.O., £500.  
*Brighton, Royal Sussex County Hospital.*—Cas. H.S., £120.  
*British Postgraduate Medical School, Ducane-road, W.*—H.P.  
*Burnley, Municipal General Hospital.*—Jun. Res. M.O., £150.  
*Burton-on-Trent General Infirmary.*—H.S., £150.  
*Cambridge, Addenbrooke's Hospital.*—Res. Anaesthetist and Emergency O., at rate of £130.  
*Canterbury, Kent and Canterbury Hospital.*—H.S., at rate of £125.  
*Cardiff, Llandough Hospital.*—Sen. Res. Surg. O., £450.  
*Charing Cross Hospital, W.C.*—Hon. Asst. Radiologist.  
*Chesterfield and North Derbyshire Royal Hospital.*—Cas. O. and Fracture H.S., at rate of £200.  
*Chichester, Royal West Sussex Hospital.*—Sen. and Jun. H.S., £175 and £125 respectively.  
*Colchester, Essex County Hospital.*—H.P., £150.  
*Connaught Hospital, Walthamstow, E.*—H.S. and Cas. O., each at rate of £100. Also Clin. Asst., 1 guinea per session.  
*Derby, Derbyshire Royal Infirmary.*—Gynaecological H.S. and Emergency Anaesthetist, £150.  
*Derbyshire Education Committee.*—Asst. School M.O., £600.  
*Doncaster Royal Infirmary.*—H.P., £175.  
*Dorchester, Dorset County Hospital.*—H.S., at rate of £150.  
*Dorset County Council.*—Clin. Tuber. O., £750.  
*Dover, Royal Victoria Hospital.*—Res. M.O., £180.  
*Edling, King Edward Memorial Hospital.*—Cons. Phys. for Children. Also Cons. Dental Surgeon.  
*Eastbourne, Princess Alice Memorial Hospital.*—Res. H.S., £150.  
*Edinburgh, National Committee for the Training of Teachers.*—Lecturer for Dunfermline College of Hygiene, &c., £500.  
*Edmonton, North Middlesex County Hospital.*—Res. Asst. M.O., £400. Also Jun. Asst. Res. M.O., at rate of £250.  
*Golden-square Throat, Nose, and Ear Hospital, W.*—H.S., £100.  
*Great Yarmouth General Hospital.*—H.S., at rate of £140.  
*Greenwich Metropolitan Borough.*—Tuber. O. for Council's Dispensary and Deputy M.O.H., £750.  
*Grosvenor Hospital for Women, Vincent-square, S.W.*—Hon. Anaesthetist.  
*Hastings, Royal East Sussex Hospital.*—Jun. H.S. and Temp. H.S., at rate of £150 and £200 respectively.  
*Hospital for Consumption and Diseases of the Chest, Brompton, S.W.*—H.P., at rate of £50.  
*Hospital for Sick Children, Great Ormond-street, W.C.*—Cas. M.O., £175.  
*Hospital of St. John and St. Elizabeth, 60, Grove End-road, N.W.*—Res. H.P., at rate of £100.  
*Indian Medical Service.*—Commissions.  
*Ipswich, East Suffolk and Ipswich Hospital.*—H.S. to the Asst. Surgeons, at rate of £144.

*Isleworth, West Middlesex County Hospital.*—Asst. M.O., £400.  
*Kidderminster and District General Hospital.*—Sen. and Jun. H.S.'s, £150 and £100 respectively.  
*Leeds General Infirmary.*—Hon. Surgeon.  
*Liverpool Sanatorium, Delamere Forest, Frodsham.*—Second Asst. to Med. Supt., £250.  
*London County Council.*—Asst. M.O. (Grade I.), £350. H.P., at rate of £120. Also Temp. Dist. M.O., at rate of £125.  
*London Hospital, E.*—First Asst. and Reg. to Children's Dept., £300.  
*London Lock Hospital, Dean-street, W.*—Surg. Reg., £100.  
*London Lock Hospital, 233, Harrow-road, W.*—Res. M.O., at rate of £175.  
*London University.*—Examinerships.  
*Maidstone, Kent County Ophthalmic and Aural Hospital.*—H.S., at rate of £200.  
*Manchester Royal Children's Hospital, Pendlebury.*—Res. M.O. and Res. H.S., at rate of £125 and £100 respectively.  
*Manchester Royal Infirmary.*—Chief Asst. to Surg. Units, £250. Also Cardiographic Registrar and Res. Clin. Pathologist, each £150.  
*Manor House Hospital, Golders Green, N.W.*—Jun. M.O., £200.  
*Marie Curie Hospital, Fitzjohn's-avenue, N.W.*—Res. M.O., £100.  
*Medical Research Council, 38, Old Queen-street, S.W.*—Research Worker, £500.  
*Metropolitan Hospital, Kingsland-road, E.*—M.O. for Jewish Out-patients, £100.  
*Middlesbrough, North Riding Infirmary.*—Asst. Hon. Surgeon. Also third H.S., at rate of £125.  
*Middlesex Colony for Mental Defectives, Harper-lane, Shenley.*—Second Asst. M.O., £460.  
*Northampton General Hospital.*—Secretary-Superintendent, £600.  
*North Riding of Yorkshire County Council.*—Asst. School M.O., £500.  
*Nottingham City.*—Asst. Tuber. O., £500.  
*Nottingham City Hospital.*—Res. Surg. O., £350.  
*Oxford County and City Mental Hospital, Littlemore.*—Med. Supt., £950.  
*Orford, Wingfield-Morris Orthopaedic Hospital.*—Res. H.S., £100.  
*Plymouth City General Hospital.*—Jun. Asst. M.O., £250.  
*Princess Beatrice Hospital, Earl's Court, S.W.*—Res. M.O., at rate of £150.  
*Princess Louise Kensington Hospital for Children, St. Quintin-avenue, W.*—H.S., at rate of £120-£150.  
*Prison Service.*—M.O. Class II., £525.  
*Puney Hospital, Lower Common, S.W.*—Jun. M.O., at rate of £100.  
*Queen Charlotte's Maternity Hospital, Marylebone-road, N.W.*—Fifth M.O. for Antenatal Dept.  
*Queen Mary's Hospital for the East End, Stratford, E.*—Two Cas. and Out-patient Officers, each at rate of £150.  
*Queen's Hospital for Children, Hackney-road, E.*—Res. M.O., at rate of £200. Also H.S. and Cas. O., each at rate of £100.  
*Royal Air Force Medical Service.*—Commissions.  
*Royal Army Dental Corps.*—Dental Surgeons.  
*Royal Chest Hospital, City-road, E.C.*—Hon. Physician.

*St. Thomas's Hospital, S.E.*—Asst. M.O., at rate of £100.  
*Salford Royal Hospital.*—H.S., at rate of £125.  
*Sheffield Royal Hospital.*—Vacancies on Res. Med. Staff, at rate of £80.  
*Southampton, Isolation Hospital and Sanatorium.*—Jun. Res. M.O., £200.  
*South Eastern Hospital for Children, Sydenham, S.E.*—Jun. Res. M.O., at rate of £100.  
*Southern Rhodesia Medical Service.*—Two Government M.O.'s, £600.  
*South Shields Ingham Infirmary.*—Sen. and Jun. H.S., £200 and £150 respectively.  
*Stafford, Staffordshire General Infirmary.*—H.P. and Cas. O., at rate of £150.  
*Stockport Infirmary.*—H.S., £150.  
*Sudan Medical Service.*—M.O., £E.720.  
*Sunderland Royal Infirmary.*—H.S., £120.  
*Torquay Borough.*—Deputy M.O.H., &c., £600.  
*Torquay, Torbay Hospital.*—Hon. Anaesthetist.  
*Walsall County.*—Asst. M.O.H., £500.  
*Warwick, Warwickshire and Coventry Mental Hospital.*—Deputy Med. Supt., £600.  
*Watford and District Peace Memorial Hospital.*—Pathologist, £250.  
*Western Ophthalmic Hospital, Marylebone-road, N.W.*—Jun. Res. H.S., £100.  
*West London Hospital, Hammersmith-road, W.*—Pathologist, £750. Also Res. Anaesthetist, at rate of £100.  
*Westminster Hospital, Broad Sanctuary, S.W.*—Hon. Anaesthetist.  
*Wigan, Royal Albert Edward Infirmary and Dispensary.*—H.S., at rate of £150.  
*Willesden General Hospital, Harlesden-road, N.W.*—Hon. Clin. Asst. to Skin Dept. Also Res. Cas. O., at rate of £100.  
*Winchester, Royal Hampshire County Hospital.*—Res. Surg. O. and H.P., at rate of £200 and £125 respectively.  
*Windsor, King Edward VII. Hospital.*—Two H.S.'s, each £100.  
*Wolverhampton Royal Hospital.*—H.S. and Asst. Res. M.O., each at rate of £100.  
*Woolwich and District War Memorial Hospital, Shooter's Hill, S.E.*—H.S., at rate of £100.  
*Worcester Royal Infirmary.*—Hon. Physician. Also Hon. Physician for Clinic of Psychological Medicine.  
*Workshop, Victoria Hospital.*—Jun. Res., at rate of £120.  
*York City.*—Asst. M.O.H., £600.  
 The Chief Inspector of Factories announces a vacancy for a Certifying Factory Surgeon at Nantwich, Cheshire.

## Appointments

- AGAR, HERBERT, M.B. Lond. & Leeds, F.R.C.S. Eng.**, has been appointed Registrar of St. James's Hospital, Leeds.
- COHEN, H., M.B. Edin.**, Junior Surgical Registrar at the Royal Victoria Infirmary, Newcastle-upon-Tyne.
- COOPER, H. ASTLEY, M.D., M.R.C.P. Lond., D.P.M.**, Deputy Medical Superintendent at the Knowle Mental Hospital, Fareham.
- DAVIDSON, ANDREW, M.D. Glasg., D.P.H.**, County Medical Officer of Health and School Medical Officer for the North Riding of Yorkshire.
- GALLOWAY, J. F., M.D. Liverp., D.P.H., D.P.M.**, Medical Officer of Health for Dewsbury.
- JOHNSTONE, A. S., M.B., F.R.C.S. Edin., D.M.R.E.**, Assistant Radiologist at the Leicester Royal Infirmary.
- LYLE, T. KEITH, M.D., M.Chir. Camb., M.R.C.P. Lond., F.R.C.S. Eng.**, Assistant Surgeon to the Royal Westminster Hospital.
- MAGNUS, J. A., M.D. Heidelberg, L.R.C.P. Edin.**, Resident Surgical Officer at the Birmingham and Midland Eye Hospital.
- MCCOERMACK, J. S., M.B. Belf.**, Assistant Tuberculosis Officer for Stoke-on-Trent.
- MACPHERSON, IAN, M.B. Leeds**, Resident Medical Officer, St. James's Hospital, Leeds.
- MONTGOMERY, J. A., M.D. Glasg.**, Resident Medical Officer at the Finchley, Hornsey, Wood Green, and Friern Barnet Joint Isolation Hospital, Muswell Hill.
- O'SHEA, JOHN, M.Ch., F.R.C.S. Irel.**, Resident Surgical Officer at the Royal Manchester Children's Hospital, Pendlebury.
- PARFITT, D. N., M.D., M.R.C.P. Lond., D.P.M.**, Medical Superintendent at the Warwickshire and Coventry Mental Hospital.
- REDDINGTON, M. P., F.R.C.S., Hon. Assistant Obstetric Surgeon** to the Woolwich and District Hospital Association.
- TRAIL, J. D., M.B. Aberd., D.P.H.**, District Tuberculosis Medical Officer for the Durham County Council.
- WEIR, J. A., M.B. Glasg.**, Junior Surgical Registrar at the Royal Victoria Infirmary, Newcastle-upon-Tyne.

Certifying Surgeon under the Factory and workshop Acts :  
Dr. A. DICKSON (Old Deer District, Aberdeen).

## Births, Marriages, and Deaths

### BIRTHS

- CRAIG**.—On June 4th, at Framlingham, the wife of Dr. D. M. Craig, of a daughter.
- DEWES**.—On June 8th, at Cromwell-road, Kensington, S.W., the wife of Dr. Gordon Dewes, of a son.
- FRIEDLANDER**.—On June 13th, at Welbeck-street, the wife of Dr. H. R. Friedlander, of Beckenham, of a daughter.
- HIGHAM**.—On June 7th, at Devonshire-place, the wife of A. R. C. Higham, F.R.C.S. Eng., of a son.
- HOBBS**.—On June 12th, at Ealing, the wife of Dr. A. N. Hobbs, of a son.
- LAWRENCE**.—On June 8th, at Wolverton, Stony Stratford, the wife of Dr. E. D. Lawrence, of a son.
- NICHOLAS**.—On Wednesday, June 10th, at Truro, the wife of Dr. P. B. L. Nicholas, of a daughter.
- PALMER**.—On June 10th, the wife of Dr. Geoffrey Palmer, Auckland, N.Z., of a son.
- PERROTT**.—On June 5th, at Stanmore, the wife of Dr. G. F. Donaldson Perrott, of a son.
- SAWLE THOMAS**.—On June 9th, at Devonshire-place, W., the wife of Dr. J. Sawle Thomas, of a daughter.
- STRATFORD**.—On June 6th, at Hampstead, the wife of Dr. Martin Stratford, of Hatch End, Middlesex, of a son.
- WILKIN**.—On June 11th, at Gloucester, the wife of W. J. Wilkin, F.R.C.S. Eng., of a daughter.

### MARRIAGES

- HUDSON—ADLINGTON**.—On June 9th, in London, Bernard Hudson, M.D., M.R.C.P., of Davos, Switzerland, to Laura Almon, younger daughter of Mr. and Mrs. Adlington, of Bath.
- LOCKETT—BRADING**.—On June 6th, at Emmanuel Church, Croydon, John Morton Lockett, M.R.C.S., to Barbara Cicely, youngest daughter of Mr. L. H. Brading, of Sutton, Surrey.

### GOLDEN WEDDING

- DAVIES—DIXON**.—On June 16th, 1886, William Thomas Frederick Davies, M.B., B.S. Lond., son of Dr. Ebenezer Davies, medical officer of health for Swansea, to Florence, daughter of Thomas Dixon. Present address: Mooi River, Natal.

### DEATHS

- DAVIES**.—On June 11th, suddenly, in London, Conway Davies, M.B. Camb., M.R.C.P. Lond.
- DU BUSSON**.—On June 11th, at Hereford, Edward William Du Buisson, M.R.C.S. Eng., aged 73.

- GILMOUR**.—On June 10th, at Woodbridge, Percy Graham Gilmour, M.R.C.S. Eng.
- MARTIN**.—On June 11th, in London, Henry Charrington Martin, M.D. Edin., of Exmouth, aged 89.
- WHYTT**.—On Monday, June 8th, at Fulham, Alexander Whytt, M.D. Edin., late of Kenley, aged 64.
- N.B.—A fee of 1s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.*

## Medical Diary

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

### SOCIETIES

- ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.**  
TUESDAY, June 23rd.  
*Pathology.* 8.30 P.M. Mr. Joseph Needham, D.Sc.: Chemical Aspects of Normal and Pathological Growth.
- THURSDAY.**  
*Urology.* 8.30 P.M. Mr. Hugh Lett: On Urinary Calculi, with Special Reference to Stone in the Bladder.
- SATURDAY.**  
*Disease in Children.* 2.30 P.M., Meeting at Addenbrooke's Hospital, Cambridge.
- BRITISH PSYCHOLOGICAL SOCIETY.**  
*Medical Section.*  
WEDNESDAY, June 24th.—8.30 P.M. (11, Chandos-street, W.), Dr. Rowland Hill: Somnifaine Narcosis.
- MEDICO-LEGAL SOCIETY.**  
THURSDAY, June 25th.—8.15 P.M. (Manson House, 26, Portland-place, W.), Annual General Meeting. Mr. J. B. Montagu: The Development in Criminal Law and Penology since 1910.
- SOCIETY OF MEDICAL OFFICERS OF HEALTH, 1, Thornhaugh-street, W.C.**  
*Fever Hospital Medical Services Group.*  
FRIDAY, June 26th.—4.30 P.M., Dr. A. Forrest: Some Aspects of Scarlet Fever and Current Methods of Control.

### LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

- MACALISTER LECTURE.**  
THURSDAY, June 25th.—9 P.M. (National Temperance Hospital, N.W.), Sir Francis Fremantle: A Doctor in Parliament.
- INSTITUTE OF CHILD PSYCHOLOGY.**  
WEDNESDAY, June 24th.—6.15 P.M. (Friends House, Euston-road, N.W.), Dr. Ethel Dukes: The Changing Needs of the Young Child. 8.15 P.M., Dr. Margaret Lowenfeld: Place of Emotion in the Formation of Character.
- BRITISH POSTGRADUATE MEDICAL SCHOOL, Ducane-road, W.**  
MONDAY, June 22nd.—2.15 P.M., Dr. Duncan White: Radiological Demonstration. 3.30 P.M., Miss L. Martindale: Radiation Therapy in Gynaecology.
- WEDNESDAY.**—Noon, clinical and pathological conference (medical). 2.30 P.M., clinical and pathological conference (surgical).
- THURSDAY.**—2 P.M., Prof. J. C. Windeyer: Diagnosis and Treatment of Some Common Obstetrical Abnormalities. 3 P.M., Dr. R. A. Young: Non-tuberculous Pulmonary Diseases.
- FRIDAY.**—2.15 P.M., Dr. A. A. Davis: Gynaecological Pathology. 2.30 P.M., Mr. Tudor Edwards: Thoracic Surgery.
- Daily, 10 A.M. to 4 P.M., medical clinics, surgical clinics or operations, obstetric and gynaecological clinics or operations.
- SOUTH-WEST LONDON POST-GRADUATE ASSOCIATION.**  
WEDNESDAY, June 24th.—4 P.M., Mr. E. Pearce Gould: Modern Operations for the Cure of Inguinal Hernia.
- FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.**  
MONDAY, June 22nd, to SUNDAY, June 28th.—WEST END HOSPITAL FOR NERVOUS DISEASES, Welbeck-street, W. Afternoon M.R.C.P. course in neurology and psychopathology.—NATIONAL TEMPERANCE HOSPITAL, Hampstead-road, N.W. Tues. and Thurs., 8 P.M., clinical and pathological M.R.C.P. course.—BROMPTON HOSPITAL, S.W. Afternoon M.R.C.P. course in chest diseases.—PRINCE OF WALES'S GENERAL HOSPITAL, Tottenham N. Sat. and Sun., course in general surgery.—PRESTON HALL, near Maidstone, Kent. Sat. special demonstrations on pulmonary tuberculosis.—Courses are open only to members.
- HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C.**  
WEDNESDAY, June 24th.—2 P.M., Mr. Charles Donald: Peritonitis: Acute and Chronic. 3 P.M., Dr. W. G. Wylie: Typhoid and Paratyphoid.  
Out-patient clinics daily at 10 A.M. and ward visits at 2 P.M.
- HOSPITAL FOR EPILEPSY AND PARALYSIS, Maida Vale, W.**  
THURSDAY, June 25th.—3 P.M., Dr. S. Nevin: Demonstration.
- UNIVERSITY OF BIRMINGHAM.**  
TUESDAY, June 23rd.—3.30 P.M. (General Hospital), Dr. E. W. Assinder: Neurosyphilis.  
FRIDAY.—3.30 P.M. (Queen's Hospital), Dr. W. Carey Smallwood: Diseases of the Red Blood-cell.

## NOTES, COMMENTS, AND ABSTRACTS

## A HOME FOR TUBERCULOUS NURSES

THE Minister of Health, accompanied by Dr. A. S. McNalty, visited the Papworth Village Settlement on June 12th to lay the foundation-stone of a new home for tuberculous nurses. Sir Kingsley Wood was introduced by Alderman Mrs. Keynes, who spoke as one who had watched Papworth's progress from inception. She said that the scheme was devised by the matron of Papworth, Miss Borne, in view of the urgent need of nurses who had lost their health. The scheme had been welcomed by the nursing profession and there was already a waiting-list for admission. Sir Kingsley Wood said that tuberculosis of every kind was steadily declining in this country. In 1911 there were over 53,000 deaths from all forms of tuberculosis; in 1935 the deaths had declined to some 29,000 out of a larger population. This meant that the death-rate per million had been more than halved in 24 years. Another criterion of progress was the number of notifications of new cases. In 1926 the total notifications were 79,654; in 1935 the figure was 59,623—a drop of 25 per cent. Many important factors had played their part in conquering the disease, like better housing and nutrition, improved hygiene, and increased knowledge. Papworth, the pioneer village settlement in this country, had its origin in the recognition of the fact that the main obstacle to the complete efficiency of sanatorium treatment was the difficulty of satisfying the need for adequate protection and care of the patient during the critical years that supervene after discharge from the sanatorium. The settlement was essentially a preventive measure as it afforded the best possible protection to the family of the tuberculous patient. It was the proud boast of Papworth that not one of the many children of tuberculous patients who had lived in the settlement had developed tuberculosis. It was now proposed, he said, to build a home for the after-care of nurses who had contracted tuberculosis in the course of their duties. Since 1930 Papworth had found it possible to employ some nurses who had originally come to the settlement as patients, either in the wards, or in the industries under sheltered conditions, during the critical years following discharge from the sanatorium; and the idea of the present scheme was to offer the same opportunity to a larger number of nurses. Sir Pendrill Varrier-Jones, the medical director, proposed a vote of thanks to the Minister for his visit.

## NEW REGULATIONS FOR THE M.C.O.G.

WHEN the examination for admission to membership of the British College of Obstetricians and Gynæcologists was first instituted, the candidates as a rule were working in recognised hospitals and were therefore personally known to members of the Council. With the development of the College at home and overseas, however, it has become necessary to revise the regulations and to make the examination not only a test of knowledge and experience but also a guide to the training of candidates. To ensure that the holders of the diploma should have had a sound clinical training, candidates must have been registered as medical practitioners, or entitled to registration, for at least three years. They must produce certificates that they have held resident appointments each for at least six months at an approved hospital in general medicine or surgery, in obstetrics, and in gynæcology. They must also submit records of 25 obstetrical and 10 gynæcological selected and personally attended cases, which they must be prepared to discuss, and two commentaries either on individual cases or on selected groups of cases. Finally there is a written examination of two papers on the anatomy, physiology, and pathology of the female reproductive organs, and on gynæcology and obstetrics, to be followed by a clinical and a viva-voce examination. Each part—the written, the clinical, and the viva voce

—will be conducted by a different pair of examiners. These revised regulations will take effect after the examination held in July.

## THE ART OF THE UNCONSCIOUS

AN exhibition of peculiar interest to the medical profession and especially to psychologists opened on June 11th at the New Burlington Galleries. The artists represented belong to the Surrealist movement, a group which, drawing on Freud and Marx for a justification and theoretical basis, endeavour to serve up their unconscious in the raw, heedless of mere striving after form or composition. This is not to say that there is no form or composition; on the contrary, the apparently superb indifference on the part of many of these displayed subconscious minds to anything other than form, reveals the link between surrealism and abstract art. We are told by Prof. Herbert Read in the catalogue, however, that "The work of art is to be judged in the first place, not by its physique, but by its imaginative scope, its intimate revelations . . . it is beside the point to talk of form and composition." This is probably why such bizarre objects and media are used; it is much harder to view a test-tube, buttons, or a kipper dangling from a few bits of wood and ironmongery as pure form than as evocative symbols; and the same applies to various "natural and familiar objects," such as the piece of dead wood found

the fulfilment of wishes that are incapable of real satisfaction: in Bacon's words "(Poesy) seems to bestow upon human nature those things which history denies to it; and to satisfy the mind with the shadows of things when the substance cannot be obtained." It is, in fact, more than an analogy to compare a hysterical fit with a work of art: both may be regarded as the indirect disguised emergence into conscious life of a repressed wish. The surrealist tries to play the part of the analyst; he strives to reconcile the conscious with the unconscious mind, even though he believes that this is only completely possible in a society based on coöperation rather than competition.

In these endeavours he is not confined purely to art. At the private view, a tall spectre in a white silk wedding-dress paraded round with her head completely enveloped in rose petals, holding in her arms a stockings dummy leg. Many previous public occasions of this movement and its predecessor appear to have begun with a practical joke and ended in riot, and there was a general air of relief that the organisers, possibly out of respect for English gentility, had restrained their subconscious minds to this mild expression. It is to be hoped that the public will be allowed to admire the pictures, many of which are extremely good, undistracted by stark ids "oop fer t'Coop."

**SNAKE-BITE SERUM.**—Messrs. Allen and Hanburys Ltd. ask us to point out that supplies of serum for use in cases of snake-bite are obtainable by day or night from their premises at 7, Vere-street, Cavendish-square, London, W.1.

**MONTAGU HOSPITAL, MEXBOROUGH.**—This hospital is proposing to start a Coronation shilling fund by which it is hoped to raise £10,000 with the object of clearing the existing debt of £4000 and helping to provide funds for the opening of two new wards at present empty.

## ADDRESSES AND ORIGINAL ARTICLES

## THE PRESENT CONCEPT OF FOCAL INFECTION\*

BY WILLIAM P. MURPHY, M.D.

*(From the Medical Clinic, Peter Bent Brigham Hospital, Boston, Massachusetts)*

IN his well-known address on the Rôle of Sepsis and Antisepsis in Medicine, delivered at the opening of the session of the faculty of medicine of McGill University in Montreal on Oct. 3rd, 1910, William Hunter<sup>1</sup> of London introduced his subject in the following manner:—

"After these prefatory remarks regarding the objects of your present studies, I pass on to the subject which I have selected as the special theme on which I desire to address you to-day. That theme is the great part played by Septic Infection—prevalent, potent, easily observed and accessible to treatment, nevertheless continuously overlooked and neglected as an important cause and complication of a whole range of medical diseases. I have selected it not only because of its great practical importance to you in your medical work in after life, but also because the story of its recognition as a great factor in causing disease illustrates in a striking way the truth of what I have just said about the importance of small things in medicine—their observation and interpretation."

"For it was while seeking to throw light on the origin and meaning of a piece of blood pigment present in an organ in the first case I ever examined for curiosities sake that I stumbled upon the chief subject and interest of my life's work—namely, that of anemia. And it was while observing as fully as I could all the features of the first case of anemia which I ever studied clinically that I came upon the curious facts that ultimately led me to recognize the importance of sepsis in medicine not only in producing anemia, but also many other medical affections."

After his observation of this one anæmic patient there followed fifteen years of experimental and pathological work in an effort to explain the meaning of that piece of pigment and the features presented by the one clinical case which led Hunter to his conclusions best expressed in his own words:

"And then I saw, but not till then—what I have since endeavoured to describe in various papers from 1900 onwards up to the present time (that is, 1910) regarding the rôle of sepsis in medicine and the importance of oral sepsis as its chief cause."

And so it is entirely fitting that the present concept of focal infection be considered by one interested in diseases of the blood in consultation with members of the dental profession in commemoration of Hunter's timely and effective discussion of the importance of oral sepsis as a cause for or complicating factor in disease.

As a result of the pioneer work by such men as Hunter,<sup>1</sup> Rosenow,<sup>2</sup> Billings<sup>3</sup> and others concerning foci of infection, we no longer are obliged to assume the pessimistic attitude in respect to the recognition, by members of the dental and medical professions, of infection and its rôle in the production or complication of disease states as was so obviously expressed by Hunter. As he predicted, however, the day has come when the presence of sepsis is sought and the importance of its control recognised.

**Sepsis in the Mouth**

Although a focus of infection may be present in various tissues of the body, it is quite generally agreed

that the mouth is the most important site. Hunter recognised the possibility of infection in various locations, but considered "oral sepsis," referring especially to the teeth, as the most important. Billings<sup>3</sup> listed ten distinct locations where focal infection may be recognised. Of these ten he lists in order of occurrence the tonsils and related tissue first; abscesses of the gums, alveolar sockets, and pyorrhœa alveolaris second. Buchanan,<sup>4</sup> Gilmer,<sup>5</sup> and Mullin<sup>6</sup> likewise believe in the high incidence and importance of oral sepsis as a focus of infection. Rosenow believes that all pulpless teeth are to be considered as foci. In a careful analysis of the infection preceding an attack of rheumatic fever in 810 children, Kaiser<sup>7</sup> found that tonsillitis or sore-throat occurred in 59 per cent., dental infection in 13 per cent., and common cold in 8 per cent. He also concludes that the most severe cases of rheumatic infection followed attacks of tonsillitis and dental infection.

Not only is oral sepsis commonly present, but it is a particularly potent source of infection owing to several unique features of the location of alveolar abscesses, as pointed out by Millin.<sup>6</sup> Whereas an infection of the tonsils, pharyngeal surface, or gum margins may drain freely so that the pus may be swallowed or expectorated, an alveolar abscess is often enclosed in a wall of unusual vascularity which readily carries into the system the toxic products of the bacterial growth. Because of the fact that it may often take the form of a blind abscess, it is probably one of the most commonly overlooked foci.

Not only are we willing now to recognise the occurrence of foci of infection, but considerable evidence has been presented to establish them as the primary causative factor in the production of certain diseases. Their rôle as complicating elements in association with various chronic illnesses is almost uniformly recognised.

In addition to Hunter, such men as Billings,<sup>3</sup> Rosenow,<sup>2</sup> Davis,<sup>8</sup> Nisson,<sup>9</sup> and Koritskiy<sup>10</sup> have been enthusiastic advocates of a causal relationship between foci of infection, especially of the oral cavity, and rheumatic conditions. From a study of 1200 rheumatic children Kaiser<sup>7</sup> has come to several interesting conclusions. Among these are the following pertinent ones: "Rheumatic infections occur slightly more often in children whose tonsils have not been removed at the time of the initial attack." "The mortality-rate is nearly 50 per cent. less in children whose tonsils had been removed at the time of the initial attack," and as previously mentioned, "The most severe cases of rheumatic infection followed attacks of tonsillitis and dental infection."

Rosenow and Meisser,<sup>11</sup> Bumpus and Meisser,<sup>12</sup> and Culver<sup>13</sup> have shown the direct relationship between oral infection and diseases of the kidney. Similar evidence might be presented in relation to other diseases, particularly from Rosenow's splendid studies carried on over a period of many years and upon which he bases his theory of "elective localisation."

Few will question the frequency with which foci of infection complicate chronic disease states. How frequently there are observed tonsil infections, either chronic or repeated acute attacks, pharyngitis, pyorrhœa alveolaris, alveolar abscesses, cholecystitis, pyelonephritis, and so forth, in association with chronic arthritis, diabetes, peptic ulcer, nephritis, endocarditis, and the various blood dyscrasias.

\* Read before the Chicago Dental Society on Sept. 17th, 1935.  
5887

In spite of the fact that these infections are now generally recognised there are undoubtedly many which go unobserved, either through failure to search intensively for them or because they are at times difficult to locate or to recognise. Even a hasty consideration of the patients in any public hospital ward or an examination of one's private case records is sufficient to convince one of these facts. Gilmer<sup>5</sup> stated in 1912 that chronic alveolar abscess is so common that few go through life without one or more such suppurations. He also estimated that 25 per cent. of jaws have suppurating cavities. In his "Practice of Medicine," Osler<sup>14</sup> stated that, "of the twenty cases of pernicious anemia which I had under observation in 1909, pyorrhœa alveolaris was present in more than half."

### The Focus and its Origin

If we may then accept as our present concept, and I believe we may, that foci of infection occur commonly, that they may at times play an important ætiological rôle in the production of disease and that they are important complications in association with many chronic illnesses, then I believe that we as physicians and dentists have several important problems to solve in the practical care of our patients. We must find means to demonstrate the presence of infection in the patient who may consult us before serious chronic illness has appeared and interest and foresight sufficient to eradicate it at that time. In the sufferer from a chronic illness we must not only locate an infection, if present, but also evaluate the importance of this infection to the patient, decide when it is best to undertake to treat the focus and what is the best means of doing so in consideration of the individual patient's difficulty.

It is not always easy to see the importance of an intensive search for an infection in an individual with vague complaints and often even more difficult to realise the importance in such an individual of an innocent appearing infection. Coates<sup>15</sup> has said that many individuals carry septic tonsils for many years without showing evidence of disease of focal infection origin. That many types of organisms, particularly various cocci, may be demonstrated in the oral cavity is well known. By what mechanism these may become pathological for the host as a focus of infection, and so a source of danger, is a problem of greater difficulty perhaps than the demonstration of the organisms. Culver<sup>13</sup> says, "the fact that streptococci are found on and in the healthy human body is not necessarily important if the normal defense mechanism remains intact, but as Williams states, if the local susceptibility is slightly greater or the coccus a little more poisonous there may be a slow growth of the cocci in the tissues with a slow cellular response resulting in a subacute or chronic infective focus or a focal infection." He further elucidates his concept as follows: "These potentially virulent organisms living a saprophytic existence have no influence on the welfare of the host until local or general tissue defense decreases; they may then invade the tissues of the host and produce the pathologic changes which their nature and the various tissue susceptibilities permit." Rosenow<sup>2</sup> believes that the patient's tissues, or tissue juices, afford the conditions favourable for streptococci to acquire and maintain particular elective localising power peculiar to the disease from which the patient is suffering.

As factors which favour the development of a focus and its effect on the individual, Buchanan<sup>4</sup> mentions fatigue, chilling, common cold, and diet. Of these

four factors fatigue is perhaps of the greatest importance as a means of lowering tissue resistance or increasing its susceptibility to infection. The importance of chilling has been questioned, but many of us believe it to be a factor in increasing susceptibility to infection under certain circumstances. The importance of the common cold can hardly be over-estimated particularly because of its frequent occurrence and the lack of real interest shown in its treatment. The present status of diet as a factor in the production of resistance to infection is summarised in an editorial in the *Journal of the American Medical Association*<sup>16</sup> as follows: "Despite the many demonstrated correlations between lack of an essential dietary factor and functional and structural change in the organism, there is surprisingly little cogent evidence of a specific relation between these factors and infection." On the other hand, as a prophylactic measure diet may be looked upon as of great value. Clausen<sup>17</sup> believes, "that an early adequate diet, particularly one rich in vitamin A, tends to prevent the development of a state of susceptibility to infection and a loss of resistance." However, he also concludes, that, "Vitamins added to an essentially normal diet or given after the onset of an infection will not improve the condition present."

Although these factors may be looked upon as contributory causes of the infection and perhaps of the patient's vague symptoms, the practical prophylaxis of a more serious illness must include local treatment of the offending infection when this has been demonstrated. So as recommended by Billings<sup>3</sup> and again by Solis-Cohen<sup>18</sup> it is important in the eradication of a focus of infection not only to remove the infection but also to build up the natural defences of the body. This may be done by combating the factors which play a part in the lowering of tissue resistance. As Solis-Cohen has further remarked, "Focal infection in the oral cavity as a rule can be eradicated by surgery, but it is not always removed when infected teeth are extracted."

### Sepsis and Chronic Disease

In the presence of established chronic disease the problem of focal infection takes on a slightly different aspect. Mullin<sup>6</sup> has said, "To find a focus of infection and to decide when its removal will result in the betterment of the patient's physical condition will ever be a difficult problem." Although this is undoubtedly true there can be little question but that all definite foci of infection should be eliminated in so far as possible in an individual having a chronic disease, whether or not one believes that this will have a direct influence upon the chronic disease state. In the great majority of instances building up the bodily resistance and improving the general state of the individual's health in conjunction with the intelligent use of any known therapy which may be more or less specific for the pathological state present will produce the greatest benefit to the patient.

Consideration as to whether or not a focus exists and as to when and how it is wisest and safest to treat it specifically will be a practical part of the management of all cases of chronic disease. Coates<sup>15</sup> emphasised the importance of coöperation between the patient's physician and the representatives of the various specialties whose advice may be required. Rarely can the specialist in a particular field decide after one or two observations of the patient whether or not the tonsils or teeth harbour a focus detrimental to the patient's health, and even though this be possible, he may not be best qualified to decide when

the infected tonsils or the tooth with a focal abscess should be removed. It will often be necessary for the patient's physician after repeated examinations and long observation to bring together the accumulated facts for consideration with the consulting specialist. With the facts available it will then be possible to decide, not only the proper time for treatment to begin, but also how treatment should be carried out in order to accomplish the greatest ultimate improvement and at the same time avoid the possibility of producing a harmful effect.

These points may best be illustrated by reference to certain situations which have been present in my own patients.

A patient came under my observation with unquestioned evidence of pernicious anæmia but complicated by gall-stones probably associated with infection in the gall-bladder. It was not possible on first examination to know whether or not the infection was an important complicating factor which might hinder improvement, but because of the severity of the anæmia it seemed best to avoid operation at that time. Consequently intensive liver therapy was instituted, but although improvement occurred it was obvious after six weeks' trial that cholecystectomy must be performed before complete recovery could be expected. A transfusion was given, cholecystectomy performed, and improvement occurred in the expected manner.

Another of my patients who has been under treatment with liver for several years and who had shown no evidence of oral sepsis developed an acute alveolar abscess while away on a vacation. She went directly to her dentist who removed the tooth without undue loss of blood, but for several days thereafter the patient felt extremely weak and upset, had a slight fever, and was confined to her bed. A few days later she came to my office, where a blood count showed a decrease of over a million red blood-cells from the level present before the operation, and other evidence of a relapse. In this instance temporary treatment until subsidence of the acute process might better have been undertaken, during which time intensive liver therapy should have been instituted, as this has been found advisable preceding any surgical manipulation so that the system is supplied with an excess of blood-building material at a time when it is most needed.

#### Disorders of the Blood

Owing to the rather frequent occurrence of oral sepsis in patients with various blood dyscrasias, the problem of its treatment becomes a very practical one. Through experience in the management of these various conditions it has been possible to recognise certain rules which if followed will give the best results for each type.

Hunter<sup>1</sup> has called attention to the frequency with which oral sepsis precedes and probably causes secondary or hypochromic anæmia. It is always advisable to search intensively for such an infection which may best be approached surgically after the patient has received a rather intensive course of therapy for control of the anæmia. If the infection be present improvement may not be entirely satisfactory before removal of the focus, but the patient will be in better condition to withstand the effect of the operation.

This situation is illustrated by the case of a patient who entered the Blood Clinic for treatment of a severe hypochromic anæmia. Previous study in the hospital had failed to reveal any other possible cause for the anæmia than an inadequate dietary intake and striking oral sepsis. During several weeks of treatment, in which time a more adequate diet was supplied, progress was slow. Her remaining teeth were carefully extracted one or two at a time until all were removed. During this time the anæmia did not increase and subsequent progress was striking. Had removal of the teeth been undertaken before iron therapy was begun, or if many teeth had been removed

at once, there would have been greater danger of a disturbing upset and I believe that progress would have been no better.

The same caution in regard to the number of teeth which may safely be removed at one time applies even more importantly in pernicious anæmia.<sup>10</sup> Although this will depend to some extent upon the degree of anæmia present and the condition of the teeth which are to be removed, it is as a rule well to remove only a few teeth at a time and, as previously mentioned, it is wise to increase, during the period of extractions, the amount of liver being used, so easily accomplished since the availability of highly concentrated and potent liver extracts for intramuscular use.

Because of severe oral sepsis, one of our clinic patients was to have all of his teeth removed in slow stages by the clinic dentist, in order that he might also be given more injections of liver than he regularly needed. Because of difficulty in leaving his work, however, he went to a nearby dentist, who extracted his remaining 21 teeth in rather slow stages; but unfortunately this was not combined with the more intensive treatment and it was found on his return for a blood count that he had lost a million and a half red blood-cells, felt weak, and had evidence of increased nerve disturbance.

In the condition known as leukæmia, alveolar abscess is not infrequently the initial indication of the disease, and it is also a frequent complication during the course of the disease. In patients with this condition the resistance to infection is low and removal of a tooth may precipitate a critical situation. It is well, therefore, to use caution in applying surgical measures to these patients. An individual who appears at your office with an abscess accompanied by malaise, fever, unexplained glandular enlargement, bleeding from the gums, or unusual pallor should have his blood carefully studied before the extraction and, if there is any suggestion of disturbance, treatment of the infection must be of a temporary nature until the patient's condition be improved by adequate means.

#### Conclusions

One might continue indefinitely to describe similar situations illustrative of the various problems encountered, but it is sufficient to realise that each patient's problem is an individual one, the solution of which will tax the physician's and dentist's skill and judgment. The greatest possible benefit will accrue to the patient if the present concept of focal infection be defined and summarised, for practical working purposes, in the following manner:—

Localised areas of tissue infection, which may be considered to constitute a focal infection, are commonly present in the human body.

The focus of infection may be a primary factor in the causation of certain disease states, and is a complication when present together with a chronic disease.

Whether or not one wishes to believe in the theory of elective localisation as an explanation of the manner in which a pathological state is brought about or even though one does not wish to consider focal infection to be an important aetiological agent, there can be little doubt but that elimination of the infection is desirable because of its influence upon the general body metabolism. The fact that treatment of a focus does not produce striking or complete improvement of a specific disease condition cannot be considered as an important argument against elimination of infections.

A focus of infection may be difficult to locate and it may be impossible at times to decide whether or

not a localised variation from normal in a tissue may be indicative of a true focus. Long observation, detailed study of the patient's various systems, and coöperative consultation between the patient's physician and the dentist or general or specialising surgeon may in the end reveal the desired facts.

When and in what manner treatment of a focus is to be undertaken may also require the coöperative consideration of the patient's problems. In general, however, the proper course to pursue is elimination or drainage of the focus at the proper time and the institution of those measures which may improve the patient's general health and so perhaps, at least indirectly, favour a decreased susceptibility to the effects of the cocci or their toxins. This may include elimination of physical and mental fatigue, avoidance of the simple infections, such as the common cold, and of unnecessary chilling, and the regulation of the dietary intake to include adequate portions of the various elements of the normal diet, and, when indicated, to suit the individual need of the patient.

### THE TREATMENT OF STAPHYLOCOCCAL SKIN LESIONS WITH TOXOID \*

BY LIONEL E. H. WHITBY, C.V.O., M.D. Camb.,  
F.R.C.P. Lond.

ASSISTANT PATHOLOGIST, THE BLAND-SUTTON INSTITUTE,  
THE MIDDLESEX HOSPITAL, LONDON

THE treatment of staphylococcal lesions of the skin is ideally carried out by a close coöperation between a dermatologist and an immunologist. Such skin infections are sufficiently common to be met with almost daily from the first moment that a student enters the field of practical medicine and they recur with such frequency even after numerous and varied treatments that the patients themselves tend to lose confidence in their many doctors. The problem of dispersing these infections is complex. There is the question of raising the general resistance to staphylococcal infection—the relatively easy task of the immunologist; there is the problem of lowering the susceptibility of the skin, and there is the necessity for increasing general bodily vigour as well as elimination of foci of sepsis including foci of staphylococcal infection in the nares (Dolman,<sup>1</sup> Valentine<sup>2</sup>). Too frequently the easy task of the immunologist is the only one exploited; often the treatment of the skin itself is not merely neglected

but is not even considered. Bearing in mind that the problem of treatment has these many aspects it is not to be expected that any one immunological antigen would be a panacea for all staphylococcal infections. A large number of antigens have had fashionable phases; most have had but a limited success; few have been used with intelligence. It is undoubtedly important to consider each separate patient as an individual before subjecting him to a long, perhaps painful, course of treatment.

#### Susceptibility of the Skin to Infection

It is not always clear what determines the susceptibility of the skin to staphylococcal infection. Nevertheless certain conditions obviously predispose to infection, and when faced with these the immunologist is not likely to achieve more than a temporary success if any at all. Examples come readily to mind. When there is a chronic aural discharge the skin of the external auditory meatus is often eczematous and unhealthy; infection readily occurs. The same applies to an eczematous skin of any type. Those who, for their living, are condemned to work in oil, such as those who bore steel, are by reason of the oil itself peculiarly liable to boils and pimples on the exposed parts of the body. Some persons have a small local unhealthy patch of skin which is the site of a recurrent boil; often this site is the collar-stud area or the scar of an old wound. Excision is the only rational treatment for such a lesion; immunology accomplishes nothing. One has also to consider what happens when soaps, cosmetics, depilatories, and even water are applied to the skin. Many date their staphylococcal infection to bathing in public baths and attribute the trouble to a germ which has been acquired there. This may be true, but it is equally true that the highly chlorinated water of public baths is to some a definite skin poison. To others, excessive sea-bathing is injurious, whilst some skin appears to be sensitive to even minor chemical changes such as are found in the washing water of different districts. The skin is also sensitive to sunlight. Suitable doses have a stimulating action and may indeed render healthy an unhealthy skin. Overdoses have the opposite effect. In the series described below were seven who, having returned from a summer holiday bronzed from head to foot, almost immediately exhibited a crop of resistant boils. The susceptibility to staphylococcal skin lesions of diabetics and of persons with deep staphylococcal foci of infection is well known.

The curative or deleterious action of ultra-violet rays on staphylococcal infections of the skin possibly supplies a key to the success which often follows the use of remedies of the protein shock type. Ultra-violet rays in suitable doses cause an alteration in local skin metabolism and may effectively reduce susceptibility to infection. The quickening of metabolic processes, the increased blood-supply to the periphery, and even the fever which shock remedies sometimes induce are known to have a tonic action on the skin. Sometimes, if the shock is great enough, the dramatic cure of a long-standing skin affection may occur. The immunologist must give full consideration to this non-specific aspect of the problem before attempting to assess the value of a specific remedy. Many specific remedies must produce part of their effect by shock but one which has a high specific action as well is most likely to achieve success.

#### Scope of the Investigation

In this report no attempt is made to compare the therapeutic effects of toxoid with those of such other

\* A report to the Therapeutic Trials Committee of the Medical Research Council.

treatments for skin infections as intensive local measures, manganese injections, and physiotherapy, which are claimed, when properly used, to give a high proportion of successes. Comparisons of this sort, involving strictly parallel series of cases treated by the respective methods, were not practicable in the circumstances of the inquiry. It should be mentioned, however, that most of the cases of boils referred to me for toxoid injections had already had courses of vaccine, whole blood, or manganese, either singly or in combination, and that many of them had been under treatment for long periods in other departments. During the period of observation of the effects of toxoid, the non-specific treatment of these cases was confined to simple local treatment.

The investigation was undertaken mainly to decide the following points: is toxoid a safe antigen for use in staphylococcal skin infections, and is its use in suitable cases followed by a good percentage of recoveries? In other words, can toxoid usefully be added to the list of remedies available for the treatment of such infections? The results given in the following survey of 200 cases, and the similar experience of other workers,<sup>1 2 6</sup> seem to provide affirmative answers to all these questions. The preparations used by me were two samples of toxoid supplied by Messrs. Burroughs Wellcome and Co. and one from the Lister Institute.

**Results**

All the results expressed in Table I. followed upon immunisation with a total dose of 0.75 c.cm. of toxoid administered intramuscularly. The total dose was distributed in four doses of 0.05, 0.1, 0.2, and 0.4 c.cm. at intervals of one week. Cases recorded as recovered have been free from relapse for periods varying from 2 to 15 months. All lesions were proved by culture to be staphylococcal in origin.

TABLE I.—Summary of Results

Lesion.	Cases.	Recovered.	Recovered or improved but relapsed.	No effect.
Boils .. ..	117	76 (65%)	29 (25%)	12 (10%)
Styes .. ..	42	37 (88%)	5 (12%)	0
Carbuncles ..	24	20 (83%)	4 (17%)	0
Pustular acne ..	9	2	4	3
Sycosis .. ..	8	0	1	7

On clinical grounds the most striking effects have been with boils, styes, and carbuncles. With regard to carbuncles, the majority have also been incised but are regarded as successes for toxoid in view of the speed of healing. In the small series of pustular acne and sycosis the toxoid did not appear to be more effective than vaccine. Forman<sup>7</sup> found toxoid of little or no use for the treatment of sycosis, but Connor<sup>8</sup> has claimed success in this disease after a long course of treatment.

**EXACERBATIONS, RELAPSES, AND FAILURES**

*Exacerbations.*—Thirty-seven patients (18.5 per cent.) (29 boils, 2 styes, 6 carbuncles) exhibited temporary exacerbations during treatment. Of these, 29 made rapid recoveries within a few weeks of the fourth injection. An exacerbation does not seem to contra-indicate treatment but rather to suggest that the individual is a sensitive subject and should be treated with doses smaller than those adopted in this series.

*Relapses.*—Twenty-nine cases (25 per cent.) of boils recovered or improved with the dose adopted but subsequently relapsed after intervals varying

from a few weeks to a few months. A second course has in most cases again procured relief, but to ensure complete freedom from infection most have had to attend for a monthly dose of 0.2 c.cm. of toxoid. Others have had subsequent successful treatment with a combination of toxoid and autogenous vaccine. Five have resisted even continuous treatment though the lesions are undoubtedly smaller and less frequent. Five cases of styes also relapsed but judgment on the reason for their subsequent recovery is difficult to make because their later inoculations were associated with local treatment in the ophthalmic department. As to carbuncles the relapses have been in the nature of small boils rather than fresh carbuncles.

*Failures.*—Complete failure was experienced in 12 cases of boils (10 per cent.). Seven of these were primarily bad subjects by reason of occupation or local skin disease but 5 appeared to have a normal skin. With pustular acne and sycosis, no marked successes were obtained.

**REACTIONS**

All in the series reported have received intramuscular injections, because subcutaneous injections in a preliminary series proved unusually painful and often produced a local reaction. The reactions can be classified into three types:—

(a) *Local* (intense redness of the skin, tenderness, and pain sometimes affecting the greater part of the arm). This occurred in 23 cases (11.5 per cent.). In a preliminary series when subcutaneous injections were made such reactions were extremely common. Some few in the present series may perhaps have been due to a small intracutaneous or subcutaneous leak when making the needle puncture.

(b) *Tiredness, headache, and aching muscular pains:* occurred in 14 cases (7 per cent.). This, as a rule, was with the first injection only.

(c) *Exacerbations (temporary):* 37 cases (18.5 per cent.). This feature has already been commented upon.

In addition, one patient, not in the series, exhibited acute anaphylactic shock when a fourth injection was given at an interval of three weeks after the third injection. He was a case of osteomyelitis who had been operated on in the interval. This severe reaction must be extremely rare for I have heard of no other case after inquiring from many other workers with a large experience of toxoid treatment.

## CIRCULATING ANTIHÆMOLYSIN

The amount of antihæmolysin has been determined in 100 normals, in 200 cases of superficial lesions before and after treatment, and in 17 cases of deep-seated lesions (osteomyelitis). The results are expressed in International Units (Tables II. and III.).

It would appear that the distribution of antihæmolysin is the same in normal individuals as in those affected with superficial lesions. But the antibody is often definitely increased in deep-seated lesions—a useful diagnostic point in obscure affections of bone. The distribution of antihæmolysin in normal individuals is approximately the same as that found by Parish, O'Meara, and Clark.<sup>8</sup> Titrations were carried out by the method described by these workers.

All three batches of toxoid had approximately the same antigenic power and definitely raised the antihæmolysin titre with the dose employed.

## RELATION OF ANTIHÆMOLYSIN TITRE TO CLINICAL IMPROVEMENT

From first principles it is apparent that an immunity to superficial staphylococcal lesions is not necessarily dependent on a high antihæmolysin titre. Seventy-six normal persons without lesions had titres of 1 unit or less and some had none at all. Relapses have occurred with titres as high as 17 units whilst no effect has sometimes been observed with titres from 8–26 units. Recoveries have occurred with titres as low as 1.5–2. The variability in the titre after a standard dose of toxoid shows that the response to the antigen is very much a function of the individual. But though the titre itself is not an accurate guide to skin immunity it provides an indirect guide to optimum treatment because there does appear to be a titre different for each individual above which it is impossible to increase whatever dose of toxoid is given. And any attempt to raise the titre beyond this point, by large doses of toxoid, usually produces a violent negative phase with a crop of lesions. The best procedure is to determine the antihæmolysin titre before and after a moderate course such as that described above and to observe the clinical effect. If the effect is good the final titre may be assumed to be the optimum for the patient and subsequent treatment for that individual is to estimate the *smallest* "maintenance dose" of toxoid which will maintain the titre at this level. If the clinical effect is to produce an exacerbation the treatment should be stopped; with cessation quite often the lesions disappear. At this point the titre should again be determined and minimal maintenance doses administered. Often such doses are as small as 0.01 c.cm. Estimation of the amount as well as the optimum spacing of doses requires considerable experience and a patient period of trial and error. It may well be that the antileucocidin titre, a procedure developed by Valentine,<sup>2</sup> will be found to be a more accurate guide to optimum treatment and a better test for the efficacy of the antigen.

After cessation of treatment the antihæmolysin titre never remains high for a long period; it slowly declines to a normal level. Most patients are free from relapses despite this decline but in others, when recurrences appear, it is wise to keep the titre high by repeated small inoculations over a long period of time.

## Comments

Previous publications on the efficacy of staphylococcal toxoid in the treatment of superficial lesions have mostly been favourable (Dolman,<sup>1</sup> Murray,<sup>4</sup> Connor,<sup>3</sup> Whitby,<sup>6</sup> Ramon and others<sup>5</sup>) and indicate

that toxoid in carefully chosen dosage is a safe antigen with a considerable chance of success. Judgment by clinical trial is notoriously difficult to make without a very large series of test and control cases. But in the present series the majority of patients had previously had many other forms of local and general treatment without success. In these circumstances the clinical results with toxoid are impressive and are in contrast to the results of Smith<sup>9</sup> who, in a parallel series, found local treatment superior to toxoid. It has long been known that the toxin-producing power of staphylococcus is extremely variable and often absent. Evidence is now accumulating to show that the toxin fractions responsible for a good antigen against superficial lesions are equally variable. Much work requires to be done before these fractions are properly separated, before the efficacy of any batch of toxoid can be properly assessed, and before a method of control is perfected. It seems probable that no one strain of staphylococcus can be relied on to supply the multiplicity of antigens which it is desirable to have present in toxoids for use on human beings. Doubtless some of the failures of toxoid treatment are due to the antigen not being sufficiently polyvalent. Comparison with foreign and dominion workers is complicated by the fact that they usually use a polyvalent antigen. Research has also to establish whether a combination of toxoid and autogenous vaccine is more effective than toxoid alone. On theoretical grounds one would expect this to be so, and I have found such a combination useful in resistant cases and for maintenance treatment.

## Summary and Conclusions

- (1) Staphylococcal toxoid injected intramuscularly is a safe antigen giving rise to a relatively small number of minor reactions.
- (2) Staphylococcal toxoid gives a good clinical result in a high proportion of cases of recurrent and resistant furunculosis, and is useful in the treatment of styes and carbuncles. It is not effective in pustular acne and sycosis with the dose employed in this series.
- (3) Staphylococcal toxoid (and any other immunising agent) is ineffective for skin lesions where the skin itself is, by occupation or disease, peculiarly susceptible to infection.
- (4) The optimum dose of toxoid is an individual factor. Those in whom the antigen produces an exacerbation should receive small doses.
- (5) The antihæmolysin titre is of small value for prognostic purposes but is of some value for estimating optimum dosage.

Through the Therapeutic Trails Committee of the Medical Research Council a large supply of toxoid has been available from the Wellcome Physiological Research Laboratories and the Lister Institute. It is a pleasure to thank Dr. R. A. O'Brien and Dr. H. J. Parish for their willing help and advice in many technical matters and for the material and reagents they have given. I wish to thank also my colleagues on the staff of the Middlesex Hospital for referring their cases to me.

ORAL AND PARENTERAL ADMINISTRATION  
OF  
PROSTIGMIN AND ITS ANALOGUES  
IN MYASTHENIA GRAVIS

By L. P. E. LAURENT, M.D., M.R.C.P. Lond.

MEDICAL REGISTRAR TO THE WEST LONDON HOSPITAL; AND

MARY B. WALKER, M.D. Edin., M.R.C.P. Lond.

ASSISTANT MEDICAL OFFICER, ST. LEONARD'S HOSPITAL  
(L.C.C.), LONDON

A NUMBER of cases of myasthenia gravis under our care have now been taking Prostigmin\* for long periods, most of them for more than a year. The time seems ripe therefore for an assessment of the value of this form of treatment, and for a discussion of dosage and frequency of administration. Above all, in view of the natural anxiety experienced by patients and their physicians as regards the possible ill-effects of prolonged treatment with the drug on the ultimate course of the case, we feel that we should put all the evidence at our disposal on record.

Working independently we have had the opportunity of using analogous drugs by injection and by mouth. The results which we have obtained by the latter method are particularly encouraging, and we believe that many mild cases will experience adequate relief from oral therapy while the more severe cases will require fewer injections.

Apart from drugs of this group some of our patients have taken ephedrine and others have taken potassium chloride in large doses daily.

ORAL ADMINISTRATION

We found a year ago that prostigmin was active orally. Much larger doses are required however if this method of therapy is employed. We found that 25-30 mg. gave us a result comparable in intensity and in duration with that seen after an injection of 0.5 mg. The largest dose which we gave orally was 50 mg. and the result was almost indistinguishable from that obtained with 1 mg. subcutaneously. At this dosage the patients began to experience a little abdominal pain and belching, and owing to inadequate supplies we were unable to continue our investigations with oral prostigmin therapy.

During the past few months we have received supplies of an analogous drug, efficacy of which by injection had already been shown. This drug, Substance 36\* of *Æschlimann* and *Reinert's* series<sup>1</sup> has now been used by us orally in gradually increasing doses with success. We found that 10 mg. gave a demonstrable though weak result. The doses were gradually increased up to 90 mg., which gave rise to no pain or unpleasant side action. With the larger doses we have given tincture belladonna M 30 at the same time, although some of our patients have taken 120 mg. without belladonna and suffered no inconvenience.

The most striking results are of course obtained with the larger doses. We have used on many occasions (in two cases daily for 3 weeks) 150 mg. of Substance 36 together with tinct. belladonna M 20. The substance was given in a solution containing 100 mg. to the ounce. An improvement is noticed

45-50 minutes after the patient takes the drug. It gradually increases in intensity until a maximum is reached two hours after ingestion. It remains maximal for 6-8 hours and then wears off gradually, some definite action being still detectable some 12-16 hours after the start. With the largest dose (150 mg.) the intensity of the improvement is equal to that observed after injection of 3 mg. of prostigmin. With smaller doses proportionate results are obtained, the intensity varying more than the duration. For instance a dose of 75 mg. produces a much less marked improvement, although its action may be shown to last 10-12 hours.

This method of treatment has many advantages. Firstly, it obviates the necessity for injections. Secondly, it gives a more prolonged action than any method which we have previously used, and it would probably be possible by giving two or three doses to keep the patient at her best for the full 24 hours. The longer action should prove particularly useful in severe cases which are liable to have dyspnoic attacks at night after the effect of an injection has worn off (see Case 6).

A FOLLOW-UP OF EIGHT CASES

We have investigated the following eight cases. Some have been under our personal care since they began taking prostigmin, others were under the care of one of us a year ago for some weeks after treatment was begun. We have re-examined them recently.

CASE 1.—A single woman, aged 42, in February, 1928, found that her arms were becoming weak and unduly fatigable. Ptosis, diplopia, and indistinctness of speech began three months later and in 1930 the legs became weak. There were short remissions in 1929 and 1930, and from 1931-33, while taking ephedrine, she improved so much that she could do light work. In September, 1934, she became much worse and was admitted to hospital on Oct. 24th, 1934. She complained of constant diplopia, and of difficulty in speaking and swallowing. She could not raise herself up in bed and could only walk a few steps slowly and unsteadily. There was bilateral, unequal ptosis, the left eyelid drooping more than the right. No tendon-jerks could be elicited.

Hypodermic injections of prostigmin 0.5 mg. were begun on admission, and the dose steadily increased till, in the middle of December, 1934, she was having an injection of 2.5 mg. daily. This was continued until April, 1935, when two injections a day were given—3 mg. in the morning and 2.5 mg. in the afternoon. Atropine gr. 1/100 was given with each injection. In November, 1935, the symptoms improved somewhat and only one injection a day was given. Since March, 1936, Substance 36 has been given daily in increasing doses by the mouth, with tincture of belladonna M 30. The effect of 200 mg. of Substance 36 by mouth equals in intensity that of 3 mg. of prostigmin, and lasts very much longer. The myasthenic symptoms are now decidedly less severe than they were when treatment was begun in October, 1934.

CASE 2.—A single woman, aged 35, noticed the first symptoms in December, 1916. Since 1918 she has had difficulty in speaking and swallowing, sometimes in breathing, and has had to be washed and dressed most of the time. She used to be taken out in a bath-chair. Remissions have been very slight. She was admitted to hospital on April 1st, 1935. There was bilateral, unequal ptosis, and bilateral limitation of movement of the eyes. She was unable to raise her arms above her head or straighten her fingers, which were always slightly flexed. The trunk and legs were also very weak, and she was only able to walk a few yards at a time, swaying from the waist.

Treatment with prostigmin and atropine was begun on April 2nd, 1935, and continued till January, 1936. Usually two injections a day of 3 mg. and 2.5 mg. were given. Since January, 1936, she has had Substance 36 by mouth in increasing doses with tincture of belladonna M 30. In her case 150 mg. of this by mouth has as intense an

\* Prostigmin is dimethylcarbamio ester of 3-oxyphenyl-trimethyl-ammonium-methyl-sulphate. Substance 36 is methyl-phenylcarbamio ester of 3-oxyphenyl-trimethyl-ammonium-methyl-sulphate. Substance 33 is dimethylcarbamio ester of 8-oxy-methyl-quinolinium-methyl-sulphate.

<sup>1</sup> *Æschlimann, J. A., and Reinert, M.: Jour. Pharm. and Exp. Therap.* 1931, xliii., 413.

effect as that of 3 mg. of prostigmin by injection, and the duration is much longer. There has been a decided, though slight, improvement in the myasthenic symptoms since treatment was begun, the general health has improved, and she has gained weight.

CASE 3.—A girl of 17, in November, 1934, found that things began to slip out of her hands, soon afterwards her legs became weak, and in January, 1935, she began to fall about. By the end of the month she was unable to sit up in bed, ptosis came on, and she had three respiratory crises. In February she improved considerably, and since then has remained in much the same condition, except for a short relapse in February, 1936, with one respiratory crisis. From April to September, 1935, she has had injections of 1.5 mg. of prostigmin daily in two doses, and from September to March, 1935, two injections of 2.5 mg., with atropine 1/100 daily. Since March 12th she has had 100 mg. of Substance 38 with tincture of belladonna  $\mathbb{M}$  30 once a day by mouth.

CASE 4.—A single woman, aged 30, has suffered from typical myasthenia gravis for eleven years. The weakness of the legs has always been the chief difficulty, but she also suffers from diplopia, ptosis, and difficulty in mastication. She has received prostigmin by subcutaneous injection since February, 1935. On an average she has three injections of 0.5 mg. daily, but during her regular premenstrual relapses she receives six to eight 0.5 mg. injections daily for a week. During remissions she sometimes has no treatment for two or three days. She also takes 4 g. of potassium chloride in half a tumblerful of water six times a day.

Her present condition is rather better to-day than fifteen months ago when she began to take prostigmin regularly. The large doses given during premenstrual relapses have never interfered with the usual rate or intensity of the remission after the menses. No new symptoms have appeared since treatment was started.

CASE 5.—A woman, aged 27, whose symptoms began in 1929, started treatment in February, 1935. She has had prostigmin daily, two or three injections of 0.5 mg. being given each day. Large single doses of 2.5 mg. with atropine gr. 1/75 have been used on many occasions, and often been followed up by 1 mg. without atropine five or six hours later when the patient had to remain active for a longer period. She also takes 4 grammes of potassium chloride in water four times a day. Examined recently, the most obvious change in her is that she has gained 2 st. in weight. Her dysphagia made normal meals impossible before treatment started and she had lost much weight. Her ptosis is never so marked as it was, and she has not had a relapse with dyspnoeic attacks, such as she had on two occasions before she began the prostigmin injections.

CASE 6.—A married woman, aged 48, has had symptoms since 1924. Ptosis, diplopia, dysphagia, and difficulty in mastication have always predominated. The limbs, although affected, remained relatively strong. She could walk a few hundred yards even when dysphagia and ptosis were marked.

In February, 1935, she began to take daily injections of prostigmin, 2.5 mg. (with atropine gr. 1/75) being used as a single dose at first. Later two or three injections of 1 mg. without atropine were given daily. After three months she suffered a relapse, dysphagia became constant when not under the influence of the drug, the arms became weaker, and attacks of dyspnoea were very frequent. In the absence of sufficient experience we could not escape the possibility that the relapse might be attributable to prostigmin. We were not able, however, to withhold the drug, as we should have liked to do, owing to the urgency of the dyspnoeic attacks. For a period of a fortnight or so 5 mg. were given daily in five doses, and it was remarkable to find this patient fluctuating repeatedly from a state of complete dysphagia and severe dyspnoea to one of relative comfort during which she ate good meals and occupied herself with light household duties. It was very gratifying during this intensive administration of prostigmin to notice a gradual spontaneous improvement, so that we were able to return to the smaller dosage, without recurrence of dyspnoea. For six months her

improvement was maintained. A further relapse occurred however during which more frequent injections were given. In April, 1935, the symptoms were more severe than ever, but relieved as usual after the injections, which were given four-hourly. She died one morning when she had received no prostigmin for five hours as she was thought to be asleep.

CASE 7.—A single woman, aged 22, had ptosis and diplopia in 1932. A few months later the weakness spread to the limbs, affecting the arms particularly. Dysphagia, nasal voice, and difficulty in mastication developed subsequently. Since March, 1935, she has taken 0.5 mg. twice a day and potassium chloride 4 g. four to six times daily. On many occasions she has taken 4.5 mg. prostigmin in divided doses within 24 hours. After a few months' treatment she was definitely worse, left-sided ptosis being constant, and diplopia more frequent. Dysphagia and dysphonia also increased. She has continued the treatment, however, taking rather larger doses, and has shown a steady improvement during the past few months. She has had no dyspnoea or other new symptom.

CASE 8.—A single woman, aged 35, gives a 16-year history of weakness of the limbs, ptosis, diplopia, and difficulty in chewing and in swallowing. The weakness of the arms has been very marked, and talking and chewing are always very difficult without treatment. She has received prostigmin since February, 1935. At first, while in hospital, she had two or three injections of 0.5 mg. daily, and on some occasions single doses of 2.5 mg. with atropine gr. 1/100. For six months after leaving hospital she had one daily injection of 0.5 or 1 mg. Lately, for economic reasons, she has reduced the dose to 1 mg. every other day. She also takes ephedrine gr.  $\frac{1}{2}$  daily and feels better on this drug. She has taken 4 g. of potassium chloride four times a day for the past year, and experiences definite improvement after each dose.

After the injections of prostigmin she leads a fairly active life; for instance, she comes up to London on a bus by herself and does a little shopping, and on one occasion she spent the afternoon at the Zoological Gardens. On such occasions she takes rather more prostigmin—1 mg. on leaving home and 1 mg. three hours later. Her condition when untreated is rather better now than a year ago. No new symptoms have appeared, and there have been no new dyspnoeic attacks. There is a notable improvement in her voice and in her ability to swallow without treatment when compared with her condition of a year ago.

#### DISCUSSION

Our experience with these eight cases has led us to the conclusion that the drugs of this group, when given in the doses which we have indicated, can be taken over very long periods without producing any unpleasant symptoms or leading to any deterioration in the myasthenic condition of the patient.

Abdominal pain can be avoided either by giving atropine with the large doses, or by giving smaller doses more frequently. There are some individual variations in this connexion. When a case begins the treatment, it is wiser to use small doses at first—e.g., 0.5–1 mg. of prostigmin by injection, the dose being increased gradually as the patient's response and susceptibility reveals itself. Soon after treatment begins, the patients who are inclined to over-exert themselves at first may find that they are somewhat weaker after the effect of an injection has passed off than they were before. It is reassuring to find that this inconvenience gradually decreases and patients find themselves as well as they usually are when the drug has ceased to act. It seems to us that ephedrine given in doses of gr.  $\frac{1}{2}$  twice a day is helpful in this respect.

We have also had the opportunity of using Substance 38 by injection. This drug has an action nearly as intense as that of prostigmin, but the duration is much shorter. For instance 0.5 mg.

of prostigmin acts in some cases from two to three hours, whereas 0.5 mg. of Substance 38, given to the same cases, does not act for more than one hour.

Of the eight cases which we have studied, five are somewhat better than a year ago and have suffered no relapses, two have had relapses from which they have recovered although prostigmin was continued throughout, and finally one case has died. The last had a very long history with previous attacks of dyspnoea before treatment began. She had two similar relapses since taking prostigmin and died in the latter of these while she was no longer under the influence of the drug.

We conclude therefore that this treatment appears to have no direct effect on the ultimate course of the myasthenia. At the same time it brings about improvement in the general health of the patients as they are able to eat more adequate meals and to lead a more varied life.

SUMMARY

(1) Prostigmin and an analogous drug (Substance 38) have been given orally with success. The action of the latter is particularly prolonged. (2) Eight cases of myasthenia have been studied after prolonged treatment with prostigmin. (3) No increase in myasthenic symptoms attributable to the treatment has been seen in any case.

We wish to express our gratitude to Dr. Blake Pritchard for his permission to include some of his cases in this investigation; to Dr. A. Morris, medical superintendent of St. Leonard's Hospital, for his permission to publish cases under his care; and finally to Messrs. Hoffmann-La Roche for supplying the drugs which we have used.

FURTHER OBSERVATIONS ON THE GOLD TREATMENT OF RHEUMATOID ARTHRITIS

BY STANLEY J. HARTFALL, B.Sc., M.D. Leeds, M.R.C.P. Lond.

AND

HUGH G. GARLAND, M.D. Leeds, M.R.C.P. Lond.  
HON. PHYSICIANS TO THE LEEDS PUBLIC DISPENSARY AND HOSPITAL

In a previous paper<sup>5</sup> we have published the results of the treatment of 100 cases of rheumatoid arthritis by injection of gold salts. Since then our knowledge of this form of therapy has been considerably extended, and the present paper deals with our experience of nearly 400 cases.

The arthritis clinic of the Leeds Public Dispensary and Hospital, where these patients are being treated, was started in July, 1934, following personal observations of the results of chrysotherapy in a few cases of rheumatoid arthritis seen in our out-patient departments. The original cases were largely treated with gold sodium thiosulphate (Crisalbine), and this drug was used almost exclusively during the first six months. Following the publication of the results in our first hundred cases, Messrs. Schering kindly supplied us with their preparation Solganal B oleosum for extended therapeutic trial, and in October, 1935, Messrs. Bayer generously offered to supply us with their preparation Lopion for the treatment of an unlimited number of cases over a period of a year. The number of patients applying for treatment increased very rapidly, and by February, 1936, over 400 cases had been seen. This paper is not concerned with patients seen after Feb. 11th, 1936,

and up to this time 374 were considered suitable for gold therapy. The present report is based upon these cases, with special reference to 300 who have received at least one full course of treatment. The 100 cases previously recorded are included amongst the present series, many of them having now had further courses of treatment.

The same criteria for diagnosis and methods of selection of cases<sup>6</sup> have been adhered to throughout and, as before, gold has been the only form of therapy, with the exception of the occasional use of aspirin and similar analgesic drugs (excluding amidopyrin preparations); we have studiously avoided all other forms of treatment. The most important modification of our method of treatment has been the gradual reduction of dosage, with regard to both the maximum single dose and the total administered in one course. We have used both the intravenous and intramuscular routes. Among our earlier cases, where crisalbine was employed, there were many who were given the heroic doses then recommended in the treatment of pulmonary tuberculosis; owing to the frequency and severity of toxic reactions the total gold salt given in one course, of approximately 12 injections, was soon reduced to 2.0 grammes, and for the last nine months this total has been further reduced to about 1.0 g., the maximum single dose being 0.1 g. These facts are of importance in assessing our results, as it necessarily follows that the early cases were given larger doses, and this may have considerable bearing both on the curative results and on the incidence of toxic reactions. In the analysis of results in terms of the different gold preparations, and the different dosage employed, a certain difficulty has arisen owing to the fact that many patients have, at various times, been treated with two or more gold salts; we have always, however, used the same drug throughout any one course.

Table I., strictly comparable with that recorded for our first 100 cases, shows the age-distribution and the age of onset of the arthritis in the 374 now under review.

TABLE I.—Age-distribution of 374 Cases

Age-group.	At onset of arthritis.	At commencement of gold treatment.	Age-group.	At onset of arthritis.	At commencement of gold treatment.
0-9	2	1	50-59	76	118
10-19	18	2	60-69	33	65
20-29	56	30	70-79	1	10
30-39	81	57	80-90	1	1
40-49	103	90	Unknown	3	0

There were 77 male and 297 female patients, an approximate sex ratio of 1 to 4. The oldest patient was 84 and the youngest 6 years.

METHOD OF TREATMENT

Of the 300 cases who have received at least one full course of gold, 113 have had two or more courses, 34 have had three or more, 8 have had four, and 1 had five courses. We have continued to give weekly injections, usually ranging from 0.05 to 0.1 g., until a total of about 1.0 g. has been given. Recently however, owing to the delayed onset of some toxic reactions, we have increased the interval between two courses to a minimum of twelve weeks, a procedure previously suggested as likely to be necessary.<sup>6</sup> During the period under review 4463 injections have been given; of the intravenous preparations 1925 were crisalbine and 1498 lopion; there were 957

intramuscular injections of solganal and 83 of Myocrysin. In terms of completed courses there were 215 of crisalbine, 147 of lopion, 92 of solganal, and 10 of myocrysin. In addition, there were 67 incomplete courses of lopion and 4 of solganal. The total number of courses, therefore, is 531, of which 460 have been completed.

The number of individual patients treated with crisalbine was 84, with lopion 80, solganal 47, and myocrysin 1, and in addition 88 received two or more of these preparations in the course of their treatment.

During the last few months we have practically confined ourselves to either 0.05 g. or 0.1 g. as the single dose for injection; we have made no attempt to modify the dosage with regard to the weight of the patient or the metallic gold content of the salt, although these are very pertinent considerations.

#### REACTIONS

We have previously stated<sup>5</sup> that slight painful exacerbations in the joints are frequent, especially during the first half of the first course of injections, and we are still of the opinion that such reactions are of favourable prognosis.

Toxic reactions are still common, but they have been much reduced both as regards frequency and severity. We recorded toxic disturbances in 45 of our first 100 cases; in the present series, which includes the original 45 toxic cases, this figure has fallen to 37 per cent., some toxic reaction having been seen in 113 of 300 patients who have completed one or more courses. Among the 113 patients who have had at least two completed courses, reactions were seen in 64 (56 per cent.); of these the disturbances were limited to the first course in 32, and in subsequent courses these patients showed no further reactions; in 18 cases where no reactions occurred in the first course they were subsequently seen in the second or third courses, while in 14 there were reactions both in the first and subsequent courses. It is of interest to note that of 46 patients who had reactions during the first course 32 (70 per cent.) had no further trouble; this observation indicates in the clearest manner a point we have previously maintained,<sup>5,7</sup> that the presence of the ordinary toxic reactions is no contra-indication to further gold treatment at a later stage.

We have analysed the cases showing toxic reactions in relation to the different preparations and have arranged them in Table II.

TABLE II.—*Toxic Reactions*

Preparation.	Patients treated.	Toxic reactions.
Crisalbine .. ..	84	49 (58%)
Lopion .. ..	80	14 (18%)
Solganal .. ..	47	12 (26%)
Multiple drugs .. ..	88	37 (42%)

Table II. does not include one case treated with myocrysin.

The multiple group includes 88 patients who were treated with two, or sometimes three, of the above preparations, but in 75 of them crisalbine was used in the first course. It is of importance to re-emphasise that the majority of our original 100 cases were treated with crisalbine in doses which we now consider to be excessive, and if over-dosage is one of the factors responsible for toxic reactions, this fact may account for the high incidence in the original series. We have, however, analysed the cases showing toxic reactions with crisalbine alone, and find that the average amount for each course was only 1.34 g.;

in terms of the total gold salt, is very little higher than the average amount of lopion or solganal which we now employ for a single course, suggesting that crisalbine may be a more toxic drug.

Table III. shows the frequency of the different varieties of reactions in relation to the preparations employed; in this table the frequency is given in terms of each course of treatment and not in terms of patients—i.e., the figures apply to courses and not to cases. The table shows that cutaneous and

\* Other skin disturbances include exfoliative dermatitis, pustular dermatitis, purpura, urticaria, herpes (2), lichen planus, and erythema nodosum.

alimentary disturbances constitute the majority of the toxic reactions. In our previous paper we analysed these disturbances in terms of patients, the figure then being 47 per cent.; of the next 200 patients 33 per cent. showed reactions, so that for the whole of our cases now presented the incidence of toxic reactions is 37 per cent. of patients, and 27 per cent. for each course of treatment; this difference is due to the fact that one patient may have had reactions in each of two or more courses. We previously recorded three deaths apparently associated with gold intoxication, and as each of these was given only a small or average dose, and the disturbance was peculiar in that it affected selectively the hæmopoietic tissues, we regarded them as being examples of gold idiosyncrasy. In the subsequent 274 cases there has been a further death of similar type; this was in a female aged 54 who developed purpura two months after her twelfth injection of crisalbine, the total amount given in the course being 1.0 g. In spite of repeated blood transfusions she died of aplastic anæmia, associated with widespread gangrenous ulceration of the œsophagus, although there was no complaint of dysphagia during life. It may be of significance that the four fatal cases were middle-aged women and each had been treated with crisalbine, though in no case was the dose of the drug excessive, even when judged by our present standards. It is, however, important to note that blood disturbances, though serious, are not necessarily fatal. We have recently seen another middle-aged female who, following 12 injections of crisalbine (total 1.15 g.), developed purpura and a progressive anæmia, with diminution of leucocytes, the blood count being: hæmoglobin, 76 per cent.; red blood corpuscles, 3,500,000 per c.mm.; leucocytes, 3000 per c.mm., of which neutrophil polymorphs were 42 per cent. Following a blood transfusion and symptomatic treatment the blood picture returned

to normal; about this time, however, the patient developed dysphagia and, in view of the extensive oesophageal ulceration found in the above-mentioned case, the condition was viewed with some alarm. On inspection the dysphagia was found to be due to a small circumscribed nodule just below the pharyngo-oesophageal junction; a small portion of this was excised and found to consist of oedematous, but otherwise normal, oesophageal mucous membrane. At the present time the dysphagia is subsiding and the patient's general health is very good. Ellman and Lawrence<sup>3</sup> have recently reported a somewhat similar though fatal case of agranulocytosis with purpura following a total course of 2.5 g. of solganal. In none of our cases showing severe toxic blood disorders have we seen punctate basophilia as described by Griffiths and Race,<sup>4</sup> but we have not systematically examined the blood of the ordinary toxic cases.

Diarrhoea of transient character has been the commonest alimentary disturbance, but the occurrence of jaundice has been a recent experience, and we encountered no examples of this disturbance in our first 100 cases. Jaundice was seen eight times and in every case it was transient, lasting from 3-4 weeks and leaving no permanent hepatic damage. The clinical picture was almost indistinguishable from the hepatitis which passes for "catarrhal jaundice."

We have found it somewhat difficult to assess the significance of cough in a group of out-patients, a large number of whom habitually suffer from this symptom in winter time. Cough is, however, one of the recognised toxic symptoms of chrysotherapy, and we have gained the impression that its incidence has been unduly high in our patients. We regard the dry, irritable, harsh cough of laryngeal type, unassociated with sputum, as being characteristic of this particular toxic disturbance; it is not accompanied by physical signs or X ray changes in the chest and is, in our opinion, without serious significance.

The rarity of albuminuria is very striking in view of the fact that it has always been considered one of the commoner ill-effects of gold therapy. There is no doubt that it was frequently seen in the early days of chrysotherapy for pulmonary tuberculosis. During the past year alone some 12,000 specimens of urine, from patients under treatment, have been tested for albumin with almost completely negative results. This suggests that albuminuria depends upon the employment of high dosage, and that it is not a necessary precursor or concomitant of other toxic reactions. The three patients showing albuminuria had no other type of reaction, and Table III. does not include 12 cases in whom albuminuria accompanied other toxic disturbances. We have seen nothing comparable with the fatal nephritis recorded by Bourgeois<sup>1</sup> and others.

It has been maintained by Williams<sup>10</sup> that toxic symptoms can be prevented by the use of calcium, for example, by dissolving the gold salt in a solution of calcium gluconate. We have already expressed the opinion that calcium does not prevent toxic symptoms, and therefore serves no useful purpose.<sup>7</sup> Our experience is based upon the treatment of 34 unselected cases; each was given a full course of crisalbine, each dose being dissolved in 10 c.cm. of 10 per cent. calcium gluconate. The 34 patients were given in all 360 injections, the average number per course being 10.5; the total weight of crisalbine given in this way was 29.75 g., the average amount per course 0.87 g. We have compared the toxic disturbances met with in this group with those in

a similar series of patients in whom crisalbine alone was used; this second group consists of 34 patients selected only to the extent of having a comparable dosage of crisalbine, cases receiving very large or very small doses being for this purpose excluded: there were 375 injections of crisalbine, the average number per course being 11; the total weight of crisalbine was 30.3 g., the average per course 0.89 g. In each of these groups of 34 patients 16 (47 per cent.) developed toxic symptoms of the usual type. These facts can be more easily appreciated from Table IV.

TABLE IV

	Patients.	Injections.		Weight of crisalbine (g.).		Patients showing toxic reactions.
		Total.	Average per course.	Total.	Average per course.	
Crisalbine with calcium ..	34	375	10.5	29.75	0.87	16 (47%)
Crisalbine only	34	360	11.0	30.30	0.89	16 (47%)

It is interesting that the case of purpura and dysphagia described above was one in whom the calcium solution was used.

RESULTS

It is difficult to give an accurate survey of our results, as we have made no selection of cases as regards the duration or severity of the disease. Many of our patients have been completely bed-ridden, and commenced attendance on stretchers or in wheeled chairs; on the other hand, many cases have been seen in the early stages of the disease. We have already pointed out<sup>5</sup> that gold treatment has no effect upon completely ankylosed joints, but no matter how hopelessly crippled the patient may be there are nearly always some joints, where the process appears to be active, which respond to treatment; for this reason the patient may remain severely disabled after treatment, but there is considerable reduction in pain and stiffness, with increased movement, and prevention of further increase in disability. We have also seen results which are little short of miraculous in patients showing the severest grades of disability, and a number of those previously bed-ridden become ambulatory, while others discard their crutches and sticks.

In recording our present results we are adhering to the classification used in our previous paper.<sup>5</sup> The term "cure" refers to complete freedom from pain and disability other than that due to bony ankylosis. Any result falling short of this standard is recorded as "marked improvement," but this group includes many patients in whom most dramatic results have been seen. The large majority of our patients fall into one of these two groups, but there are others who have shown improvement of a less striking character, and these are classified as "slight improvement."

TABLE V.—Results

Result.	Cases.	Per cent.
Apparent cure .. ..	25	8.3
Marked improvement ..	208	69.3
Slight .. ..	45	15.0
No .. ..	17	5.6
Worse .. ..	1	0.3
Died .. ..	4	1.3

In addition to the effect on the joint condition, there is a noteworthy improvement in the general

health in the majority of the patients, with an increase in appetite, gain in weight, and a general feeling of well-being and better health, and this is usually associated with a fall in the blood sedimentation-rate.

We have further analysed our results in relation to the different gold preparations used, and they are summarised in terms of percentage in Table VI.: this table refers to the results in regard to completed courses of treatment, irrespective of the number of patients.

TABLE VI.—Effects of the Gold Preparations (Completed Courses)

Result.	Crisalbine.	Solganal.	Lopion.
	Per cent.		
Cured .. .. .	22.5	0	3.8
Marked improvement ..	50.6	77.0	67.0
Slight .. .. .	18.2	10.4	20.4
No .. .. .	3.4	12.6	8.8
Worse .. .. .	1.1	0	0
Died .. .. .	4.2	0	0

In Table VII. an analysis of the results in the 300 patients who have completed one or more full courses of treatment is shown; this includes those who have been treated with two or more different drugs ("multiple"), and it excludes one case treated with myocrysin only (showing marked improvement).

DISCUSSION

The opinion of most physicians who have recorded their experience of gold in the treatment of rheumatoid arthritis is that chrysotherapy is the most notable advance in the treatment of this hitherto incurable disease, a view which is amply borne out by our further experience, and we are at a loss to understand the poor results recorded by Mester<sup>8</sup> in a small series of cases.

It is equally recognised that the great disadvantage of the treatment has been the frequency and occasional severity of toxic complications. During the past two years we have satisfied ourselves that many of these disturbances are due to over-dosing, and a modification of technique in the direction of reduction of dosage has not affected the curative results to any significant extent, while the toxic disturbances have been rendered less frequent and much less severe. We have, therefore, modified a view previously expressed.<sup>6</sup>

Our results up to date are that 78 per cent. of the cases show either apparent cure or marked improvement, while some improvement is shown in a further 15 per cent. The corresponding figures for our first 100 cases were 69 per cent. and 23 per cent., so that from the curative point of view the original promising results have been fully maintained, or even bettered. Conversely, the total number of toxic reactions has been reduced from 45 per cent. to 37 per

cent., and even more important is the fact that serious reactions are much less frequent, the mortality having fallen from 3 per cent. in the first 100 to 0.36 per cent. in the subsequent 274 cases, there having been no fatality among the last 200 patients. Owing to the large size of the clinic, we have not been able to adopt elaborate measures for the anticipation and prevention of toxic symptoms, such as those suggested by Savy<sup>9</sup>—i.e., the blood sedimentation-rate, differential blood count, with a von Bonsdorff count—after each injection, but we have had to rely mainly upon our clinical experience.

In the treatment of toxic reactions we still rely upon symptomatic measures, and we are not familiar with any specific antidote. The problem of idiosyncrasy remains unsolved, and in our experience cannot be predetermined. According to Ellis<sup>2</sup> idiosyncrasy is seen "about once in thirty cases," but we have found it to be less frequent than this. The development of any blood disorder is probably a particular example of this phenomenon, and although not always fatal should be regarded as contra-indicating further gold treatment. Exfoliative dermatitis also contra-indicates further treatment as it is always a serious condition; it has fortunately only occurred once in our experience. We have previously shown<sup>8</sup> that hypertension and arterio-sclerosis do not prohibit gold treatment, but we consider patients with gross hepatic or renal disease to be unsuitable.

It has frequently been claimed that the toxicity rate is higher with intravenous than intramuscular injections: we have always doubted this,<sup>6</sup> and it is significant that in our large experience lopion, an intravenous preparation, has shown the lowest incidence of toxicity (Table II.).

SUMMARY AND CONCLUSIONS

1. Gold treatment was used in 374 cases of rheumatoid arthritis.
2. Cure or marked improvement occurred in 78 per cent., and slight improvement in a further 15 per cent.
3. Reduction in dosage has been followed by considerable reduction in toxic reactions without sacrificing the therapeutic effects.
4. There is no notable difference in the curative effects or toxicity between intravenous and intramuscular methods of administration.
5. The maximum single dose should not exceed 0.1 g., and the total for each course not more than 1.0 g. All patients should have at least two courses, and the interval between courses should be not less than three months.
6. Chrysotherapy is the most important form of treatment for rheumatoid arthritis.

PROVIDENCE FREE HOSPITAL, ST. HELENS.—This hospital, which is conducted by the Poor Servants of the Mother of God, needs £30,000 for extensions. There is a scarcity of private wards, and the nurses have to work and live under trying conditions, as the accommodation is insufficient for the number engaged in the institution.

## THE "ACCIDENTS" OF GOLD TREATMENT IN RHEUMATOID ARTHRITIS

By G. J. VILLIERS CROSBY, M.D. Camb.

CLINICAL ASSISTANT AT QUEEN MARY'S HOSPITAL, STRATFORD;  
HONORARY PHYSICIAN TO ST. PETER'S HOME, KILBURN

DURING the past three years there have been a number of publications in this country upon the use of gold salts in the treatment of rheumatoid arthritis, notably contributions by Forestier, Slot, Pemberton, and Hartfall and Garland. At the same time, much work on this subject has been performed by numerous clinical investigators on the Continent. The results of this treatment have been found to be fairly consistently encouraging, especially in the so-called rheumatoid type of arthritis.

During the past two years I have treated a series of cases of arthritis of various types with similarly hopeful results, using mainly two preparations of gold salts, Allochrysin and Solganal B Oleosum. The completed cases in this series number 27 in all, and the Table shows these results grouped according to the patients' ages. The cases were not specially selected for treatment and it is interesting to note that not only those of recent origin but also those of fairly long standing received benefit. It is remarkable that out of 27 cases only 1 was in the group aged 30-40. In this connexion it should be remarked that bony deformity is in no way ameliorated, as evidenced by X ray examinations before and after treatment, but that improvement seems to be due to holding up of the active inflammatory process. My findings, therefore, as regards the results of treatment, very largely tally with those published by previous workers.

Total ..	3	1	8	7	6	2	27

A study of the articles published on the subject has led me to conclude that the reactions, or, as they are called by the French writers, "accidents," consequent upon the use of gold salts have been somewhat glossed over. It has become apparent to me that these unfortunate occurrences are considerably more common than most of us care to admit. This seems to be especially the case in the treatment of rheumatoid arthritis, more so in fact than in the treatment of other conditions—e.g., tuberculosis, lupus erythematosus, &c.—with the same medicaments. I have found the incidence of reactions to be high in spite of extreme care in dosage and concurrent treatment. It is, therefore, the object of this article to describe these accidents and to determine, if possible, how far their incidence justifies the use of this form of treatment.

### ETIOLOGY

In the early days of the use of the organic arsenical preparations the problem of toxic reactions was out-

standing, and there seems to be a close analogy between these and the accidents occurring as the result of chrysotherapy. In the latter the phenomena are very variable, both in their nature and in their severity and danger. The theories of their causation are multiple and the amount that has been written is vast and confusing.

Certain of these reactions are said to be due to a phenomenon that has received the name of "biotropism." The term is used to describe what is believed to be an increase in the virulence of "latent organisms" excited by such agents as X rays, gold, arsenic, or bismuth. It is difficult to understand exactly the nature of these organisms or the manner in which they are excited, but there seems to be little doubt that there is a certain group of symptoms not directly attributable to the toxicity of the gold itself. The condition was first described by Milian, and later by a number of other observers, notably, Heuk and Vonkennel, and Coste, Forestier, and Bourderon. Forestier has described biotropism as "the revelation of symptoms of another disease hitherto unsuspected. In a few cases, boils and herpes zoster have been noted, all apparently due to latent disease." Among these biotropic reactions are included erythema, grippe aurique or gold influenza, herpes zoster, neuralgia, and conjunctivitis. Contrary to the opinion of the German authorities, the French authors add to these bronchitis, focal reactions, and agranulocytosis. The remaining reactions are believed to be due rather to the toxicity of the gold preparations themselves. In this connexion it is interesting to note that Freund attributes the skin conditions observed during gold treatment to a toxic accumulation of products of decomposition due to the curative process.

It seems possible that some phenomena may be allergic in nature, and both Feldt and Tzanck have put this forward as a hypothesis. It is well known that certain drugs may act as allergens; among them are aspirin, antipyrin, cocaine, mercury, arsenic, and strychnine (van Leeuwen). That gold might be included in this group does not require a great stretch of imagination, although it is clear that such an explanation will not cover the whole range of phenomena that may result from the administration of the drug.

### TYPES OF REACTION

The importance of differentiating between the various kinds of reactions lies in the decision whether to continue treatment or not. Whereas it is claimed that the biotropic type of case comes to no harm if the treatment is continued, there can be no doubt that the toxic type is likely to be most unfavourably affected. My own experience has led me to believe that it is always wisest to suspend treatment, at all events temporarily.

A method of differentiating between the so-called biotropic cases and the toxic states has been described by Hinault and Mollard, especially with regard to the skin conditions, where diagnosis may be difficult or even impossible. They suggest the intradermal injection of 0.2 c.c.m. of a gold salt (crystalbine). A positive reaction is said to take place in the majority of toxic cases and a negative reaction where biotropism is present. No doubt a positive reaction might also be expected if allergy were the cause, but I have at present no experience of this procedure.

It is to Hinault and Mollard that I am particularly indebted for their brilliant classification of gold "accidents." Following their example, I will classify

these manifestations from a clinical point of view, avoiding as far as possible further reference to their causes.

*Immediate reactions* are not common. The most frequent is a general malaise with a little giddiness and headache, which passes off after a few hours. This has been noticed in 9 of my cases. Symptoms of gastro-enteritis (nausea, vomiting, and diarrhoea) occurred in 1 case. In 2 cases these immediate effects occurred after injections of allochrysin and were not noticed when solganal was substituted, an important point in favour of the latter. Other immediate reactions which have been described are acute shock with pallor, imperceptible pulse, &c., acute pulmonary oedema, laryngeal oedema, marked asthma, and severe vertigo. In these cases, treatment must, of course, be suspended, but such severe phenomena are of extreme rarity.

*Focal reactions.*—In a number of cases exacerbation of the pain and swelling has been noticed in affected joints. This reaction must be taken as a favourable sign. It is noticed normally after 4 or 5 doses have been given and cannot be fairly classified as an accident. It is not, however, present in every case. In my series, 9 patients complained of exacerbation of their rheumatism. It has been found advisable to warn patients of this possibility at the outset of their treatment.

*Rise of temperature* may occur in conjunction with the focal reactions or it may follow an injection. At times the increased temperature may continue for some days, in which case the onset of a skin reaction or digestive disturbance may be suspected. According to Hinault and Mollard, a continued high temperature should suggest an immediate blood count, as it may be the only outward sign of an incipient agranulocytosis (vide infra). A further cause may be a "gold influenza," of which I have had 2 cases in my series. One of these patients continued to show occasional exacerbations of temperature during her course of treatment, until she finally declared herself with an extensive exfoliative dermatitis. This case is described later. Curiously, the other case also eventually suffered from exfoliative dermatitis. Whether this is purely a coincidence cannot be determined. I am in complete agreement with Fellow who considers that high febrile reactions are quite unnecessary for the success of the treatment.

Among *gastro-intestinal and hepatic reactions* may be numbered gastric and intestinal pain, vomiting, diarrhoea, and jaundice. The differential diagnosis of these symptoms may not always be simple. Previous gastro-intestinal derangements have been cited as a possible contra-indication to the treatment, and severe hepatic insufficiency—e.g., cirrhosis or hepatitis—is undoubtedly so. In the allergic type of case, instead of producing an urticaria the treatment may possibly cause a reaction in the form of an attack or attacks of gastro-intestinal disorder. Hinault and Mollard believe that frequently occurring gastric derangements are usually due to transient hepatic insufficiency. Jaundice, on the other hand, is a definite indication of this; it is usually simply catarrhal, but blood examinations should always be undertaken immediately the symptom appears. Fatal icterus gravis has been recorded, and acute yellow atrophy is not unknown, especially in cases where an unsuspected hepatic lesion is present. Such accidents have luckily been extremely rare, and, with proper foresight, should not occur. At various stages of treatment 2 of my cases presented gastro-

intestinal symptoms. These have usually appeared shortly after injection and have been transient in their effect. In one case the treatment was discontinued for a fortnight as the trouble was somewhat persistent.

*Renal reactions.*—It has been noted that 75–80 per cent. of the gold injected is eliminated by the kidneys, and also that renal insufficiency is a definite contra-indication to the treatment. It does not seem unlikely, therefore, that the kidney substance may become affected during the course of treatment, even to the extent of the production of a toxic nephritis. Such accidents are by no means unknown and have been described by various workers. Routine examination of the urine is therefore an absolute necessity, and I have made it a practice to examine a specimen before every injection. Albuminuria is not infrequent during treatment and has occurred in 5 of my cases. It is usually found in small quantities only and as a general rule has very little significance. In each of the 5 cases, a further examination has been made for casts in the urine and in none have these been found. In one case, an unsuspected infection by *Bacillus coli* was discovered; albumin was only found here at the conclusion of treatment when the arthritic condition was greatly improved. Oedema has not been noted in any case. Where albumin has been present in appreciable quantities treatment has usually been suspended for a short time, as a result of which it has usually cleared up entirely and has not recurred on resumption of treatment.

*Affections of the skin.*—The simplest form of skin reaction is a mild itching, sometimes severe enough to be dignified by the name pruritus (4 cases). In a number of cases in the series this has been referred especially to the back of the neck. Urticaria is said to be fairly frequent but has not occurred in any of my cases. Mild local and sometimes generalised erythematous occur, which may be very itchy and at times painful. Reference has already been made to the difficulties of differentiation between the biotrophic and toxic types. An erythema, rather suggestive of a mild eczematous dermatitis, has been noticed, especially in 2 cases. In the former of these, itching was somewhat severe and a raised papular eruption was present, particularly on the forehead just above the eyebrows. This seems to be a favourite site for the appearance of gold rashes. The second case was peculiarly instructive.

The patient, aged 79, had an unusually severe arthritis of the infective type, with raised red cell sedimentation-rate, swollen and extremely painful fluctuating joints, and a temperature occasionally reaching 99.4° F. There was a very marked improvement after a course of injections of solganal given in doses of 0.1 g., totalling 1.8 g., over a period of four months. Towards the end of the treatment, a little irritation of the ankles and shins was noticed and the skin was generally dry all over the body. Although the sedimentation-rate was still high and the arthritis was by no means cured, it was decided to discontinue treatment, partly owing to the patient's age and partly because her arthritis was very much more bearable than it had been. The irritation around the ankles was very variable, but from time to time a mild papular erythema appeared which gradually became semi-permanent in patches. These patches then became scaly and very itchy and one or two similar eczematous places appeared on the thigh. A blood count revealed an eosinophilia of 15 per cent. Suddenly, some six weeks after the last dose of solganal had been given, a generalised papular erythema appeared on the body; this was very variable in its intensity and distribution, almost in the manner of an urticaria. Glucose in large quantities, sodium thio-sulphate (Ametox) by intramuscular injection in doses of 0.45 g. for 10 doses, liver extract, and calcium gluconate

were given, and the condition slowly improved. The patient's general health remained good and the rheumatism showed a general improvement. The long interval between the last dose of gold salts and the appearance of the erythema is of particular interest.

Skin eruptions resembling lichen planus have been described, notably by Gougerot, Burnier, and Photinos, and cited by Hinault and Mollard, and by Bertier and Boquillon. One such case occurred in my series. The diagnosis became, in my opinion, so evidently one of the lichen planus, with lichenification on the inner surface of the cheeks, tongue, &c., that I was at first inclined to believe that the condition had no connexion with the administration of gold. It was only when I found the references quoted above that I realised the possible relationship. The condition cleared up very satisfactorily and quite spontaneously. As usual, the mucous lichenification seemed to be more resistant than the cutaneous. Herpes labialis was noticed in 3 cases; I have seen no case of herpes zoster, and herpes simplex was seen in 1 case about two months after the conclusion of treatment. Conjunctivitis has been entirely absent.

Exfoliative dermatitis of a particularly severe degree may occur during the course of treatment and is without doubt one of the more worrying and serious accidents to be anticipated. The condition has been described under a variety of names: erythrodermia, erythrokeratodermia, toxic dermatosis, &c. It is heralded by a simple erythema which gradually becomes oedematous, with a papular and then possibly a vesicular eruption superimposed. This spreads fairly rapidly, and is accompanied by a general reaction with raised temperature and pulse, malaise, and headache. The face becomes oedematous and erythematous, and there may be exudation, generally near the skin folds. Irritation is intense, and there may be considerable pain necessitating the use of morphia. The acute stage may last as long as four or five weeks, after which a generalised exfoliation takes place, usually in large flakes. The palms of the hands and soles of the feet are chiefly affected, and often simultaneously the mucous membrane of the mouth. The condition must be recognised as of really serious import, for a number of deaths have been reported, though recovery seems to be the rule. I have had the unfortunate experience of having had 2 cases of exfoliative dermatitis in my series.

One of these received a total dose in one course of treatment of 1.9 g. solganal and had been rather troublesome throughout. She had febrile reactions (gold influenza) followed by bronchitis of an asthmatic type and finally the toxic dermatosis. Unfortunately, in this case I was swayed by the advice given by certain authorities, that treatment should be continued in full doses where biotropism occurred. As a result of this experience, my opinion on this matter is now entirely reversed. Treatment consisted of large quantities of glucose by the mouth— $\frac{1}{2}$  lb. a day—and ametoxy by the mouth and intravenously. Local treatment was according to symptoms and was purely palliative. Recovery was complete and practically uneventful, although occasional rises of temperature occurred from time to time (up to 100° F.). It is satisfactory to note that this patient's arthritis, which had been completely crippling, improved enormously.

The second case had received a total dosage of only 0.8 g. allochrysin. The history of onset was very similar to that of the first case, but here oedema was not so great and there were no warning signs beyond occasional irritation. It so happened that, owing to Christmas holidays, the patient had not attended for treatment for nearly a fortnight and had not considered the itching severe enough to report. She was put to bed immediately, following which the condition progressed almost exactly on the lines already described. Treatment was as with

the first case. Exfoliation was particularly severe, especially of the hands, and a secondary furunculosis gave a considerable amount of trouble. Recovery was slow and is not complete after a year. The skin still tends to be rough, and blepharitis is particularly troublesome. She has also had minute patches of alopecia areata, which have now disappeared. It should be noted that she had had a similar trouble previously. In this case again there is now no complaint of rheumatism.

It is useless to under-estimate the severity of the reactions here described, and it must be confessed without reserve that both these cases gave much anxiety, especially during the acute periods. Both patients, however, had had long-standing rheumatoid arthritis. The former of these patients, moreover, on being questioned since her recovery, has stated that it was worth while going through such discomfort to have her rheumatism so much improved; the latter is not quite so sure. Study of the subject suggests that the condition is by no means common, and it is some consolation to know that the occurrence of two such cases in a comparatively short series is not likely to be repeated.

*Stomatitis* seems to occur with some regularity, and may be ulcerative (3 cases). Dysphagia and sore-throat occasionally result and have been noticed in two of my cases. There may also be an unpleasant metallic taste in the mouth and loss of taste (2 cases). Lichenification in the mouth has already been described. Marginal glossitis, ulceration, and swelling of the gums and also superficial vulvitis and ulceration about the anus have been described by various workers.

*Bronchitis*.—Coste, Forestier, and Bourderon have drawn particular attention to this, and believe it to be a true biotropism. It is considered by them to be particularly associated with the use of solganal. I have had one case in which a bronchitis of an asthmatic type was noted, and it is possible that a patient who developed broncho-pneumonia some weeks after cessation of treatment may also have been influenced by the administration of gold. This, however, happened at a time of year when respiratory infections were prevalent.

*Blood conditions*.—Of all accidents due to the use of gold, the hæmopathies are without doubt the most serious and the only ones with a high mortality; luckily they have the advantage of being extremely rare. As evidence of their rarity it may be stated that only 30 cases of purpura have been described in all, and these of all types inclusive of the simple benign variety. Purpura hæmorrhagica, agranulocytosis, and aleucia hæmorrhagica (malignant thrombocytopenia) have all occurred and have all been attended by a high mortality.

One patient under treatment has developed purpura simplex after a total dosage of 1.9 g. of solganal. This patient was suffering from severe rheumatoid arthritis with extreme deformity. She had, moreover, marked anæmia of a secondary type (hæmoglobin 54 per cent., colour-index 0.64) and a relative lymphocytosis with only 35 per cent. of neutrophils in a total leucocyte count of 7200 at the beginning of treatment. I have no doubt, in the light of my present knowledge, that I should not have instituted chrysotherapy in this case. She developed an absolute leucopenia, which has improved since the treatment ceased and with the administration of nuclein, but she still has a neutropenia. She had always been subject to epistaxis. Four months afterwards she still occasionally has slight subcutaneous hæmorrhages. She has, moreover, complained of mild papular erythema and stomatitis from time to time. The painful joints have, on the other hand, been very much improved, and the patient has been able to carry out her duties as a filing clerk in a bank with increased efficiency and with very little absence from work.

The possibility of the incidence of blood dyscrasias must be recognised as an indication of the necessity for frequent blood counts. Coste and Bourderon have made it clear that it is only by neglect of signs of intolerance that the majority of these cases arrive at the stage of severe blood affection. Most of the cases occur in women with hepatic disease.

#### CONCLUSIONS

It has been seen that accidents associated with treatment by gold salts are protean in their character and are, moreover, by no means rare. If, however, all reasonable care is taken in the supervision of the treatment, if careful inquiry is made into the subjective phenomena experienced by the patients themselves, and if the urine and blood are regularly examined, no very serious complication is likely to arise. Possible exceptions to this rule are the skin rashes which may occur suddenly, unexpectedly, and even, as noted above, some weeks after administration has been discontinued. It has been said that eosinophilia is a warning sign, but there is some doubt about this. In only 2 cases in my series were polymorphonuclear eosinophils much preponderant. One of these cases at no time showed any sign of either biotropic or toxic reaction, the other case has been described above as suffering from an erythema of an eczematous type. Coste and Bourderon believe that no conclusion can be drawn as to the significance of excess of eosinophil cells. Numerous authors, on the other hand, have advised caution in cases where eosinophilia rises above 8 per cent.

From the foregoing, it is obvious that treatment of rheumatoid arthritis with gold salts is attended by not a little risk. I have, however, at present no doubt that this form of treatment is quite the most potent now available. It is sincerely to be hoped that some means may be found to reduce the toxicity of the salts either by a change in their chemical composition or by the concurrent administration of some adjuvant. It is my practice to administer calcium gluconate and liver extract by the mouth throughout treatment, but I am very doubtful about their actual efficacy. In all cases of severe reaction I have given ametox by intravenous or intramuscular injection, but without obvious result. I have also given preparations of vitamins A and D. It has been suggested that irradiation with ultra-violet rays might be helpful as a means of prophylaxis against the skin reactions, but I have no experience of this.

It seems that chrysotherapy should only be undertaken when the case is severe enough to warrant such a very real risk, which should be explained to the patient before treatment is instituted.

The greater part of this work was done at Queen Mary's Hospital, Stratford, E., and I am greatly indebted to Dr. Ernest Fletcher, honorary physician to the hospital, for permission to publish these results and for the great help and encouragement he has given me; also to the committee of the hospital for financial assistance in carrying out the work.

## THE CARDIAC OUTLINE

BY T. SKENE KEITH, M.B. Lond.

PATHOLOGIST TO THE NATIONAL HOSPITAL FOR DISEASES OF THE HEART, LONDON

THE almost routine use of the X rays for the inspection of the heart and great vessels postulates a more accurate knowledge of the anatomy of those organs than is supplied by the ordinary text-books. A single stereotyped anatomical description of the surfaces and contours of the "normal" heart is of little value in the widely varying conditions found by the X rays in even ostensibly healthy subjects.

The following anatomical investigations were undertaken to establish what were the normal type or types of heart silhouette as seen from the front at autopsy. It is not claimed that the position of the heart at autopsy is identical with that which it occupied during life—witness the empty shrunken aorta and the distended superior vena cava—but a very short experience of examining hearts in situ directly after the chest has been opened will impress the observer with the great difficulty there is in making the heart take up and retain a new position until and unless the lungs, diaphragm, or great vessels have been damaged. That there is a fair degree of agreement between the outline of the heart as seen at autopsy and that obtained in orthodiagrams or telerradiograms will, it is hoped, be shown in a subsequent paper on the diseased heart.

#### TECHNIQUE

This has been previously described.<sup>1</sup>

The skin and soft parts of the anterior thoracic wall are resected widely; the ribs are cut in the anterior axillary line, for which purpose a heavy pair of gardener's secateurs are invaluable, and removed together with the sternum. Great care is needed in removing the upper end of the sternum so as to avoid cutting the innominate or other large veins. If cut they must be closed with Spencer-Wells forceps as the leaking blood badly obscures the parts. The pericardium is now reflected and dissected off the aorta, superior vena cava, and pulmonary artery. The distance to which this can usefully be done varies in different cases and care is again necessary to prevent loss of blood. The lungs are now gently drawn aside and the whole anterior surface of the heart displayed. A sheet of plate glass with one or more vertical lines ruled on it is now laid over the heart, one line being placed as nearly as possible in the middle line of the body. On this sheet of glass the outline of the heart and its various parts and of the great vessels is drawn with a dermatographic pencil, the greatest care being taken to keep the eye vertically above that part of the heart which is being recorded. The diagram thus obtained is then transferred to a sheet of paper (Figs. 2, 3, 4, 5).

In all some 150 diagrams are available, 78 from hearts not associated with heart disease and over 70

FIG. 1.

FIG. 2.

FIG. 3.

FIG. 1.—Composite diagram of 10 silhouettes of hearts of Type I, showing how the arbitrary normal limits were arrived at. Each line represents the outline of a single heart. In making the diagram the diagrams have been freely moved to the right or the left as well as upwards or downwards, but their inclination to the horizontal has been most rigidly preserved.

FIG. 2.—The heart silhouette from a single Type I, inclined heart. The grey background represents the area within which the outlines of the 28 hearts fell.

FIG. 3.—The heart silhouette from a single Type II, horizontal heart. The grey background represents the outlines of 9 hearts of this type.

from cases of morbus cordis of various types. In the present paper it is proposed to deal only with the more or less normal types.

RESULTS OF OBSERVATIONS

To begin with general observations: The first is the prominence of the superior vena cava, which, even when not grossly dilated, is still of considerable size (average width 1.75 cm.). The next is the difference between the anterior surface of the heart as seen in situ and as seen after the removal of the "pluck"—i.e., the trachea, oesophagus, heart, and lungs from the body. In situ little, if any, of the left auricular appendage is seen; after the removal of the pluck it is the most prominent feature of the anterior surface of the heart. This rotation from

left to right of the heart after its removal from the thorax, together with the emptying and collapse of the superior vena cava have been responsible for much confusion in the anatomical interpretation of skiagrams of the thorax.

The anterior surface of the heart mass that corresponds to the shadow seen by the X rays is made up of the superior vena cava, the aorta, the pulmonary artery, the right auricle, the right ventricle; in 9 cases a minute tip of the left auricular appendage, the left ventricle; and in 4 cases a millimetre or two of the inferior vena cava. The margins of this mass are made up as follows:—

The right margin is composed, from above downwards, of the superior vena cava, the right auricle, and in the four cases already mentioned the inferior vena cava.

FIG. 4.

FIG. 5.

FIG. 6.

FIG. 4.—The heart silhouette from a single Type III, globular heart. The grey background represents the outlines of 8 of the 9 hearts of this type, the remaining heart though of typical outline was so small that its inclusion would have stultified the diagram.

FIG. 5.—A heart silhouette from a single Type IV, square or conus heart. The grey background represents the outlines of the 13 hearts.

FIG. 6.—The silhouette of a unique vertical heart. From a male, aged 37. Died of shock from multiple injuries; no disease of any sort.

The *diaphragmatic surface* is made up of the right auricle, the right ventricle, and in 26 cases a few millimetres of the left ventricle. In 4 cases, as noted, the inferior vena cava formed the extreme right of this margin.

The composition of the *apex* was determined by the position of the anterior descending branch of the left coronary artery whose course marks out the position of the interventricular septum. Unfortunately the importance of this was not at first realised so that in only 33 of the diagrams under review was the course noted. In 26 of these cases the apex is formed by the left ventricle, in the remaining 7 the longitudinal axis of the heart passes through the artery at the apex which therefore consists of the septum rather than of either ventricle. In no case was the apex formed by the right ventricle.

The *left margin* is formed by the left ventricle below and the conus arteriosus, or infundibulum of the right ventricle, above. In 9 cases, as already noted, the tip of the left auricular appendage was seen; its actual position varied: in 1 case it lay against the left ventricle, in 2 cases at the point where the left ventricle and the conus meet, and in the remaining 6 cases it lay against the conus itself.

The upper part of the left margin of the heart, where it is in relation to the great vessels, is the area where this particular method of research gives the least satisfactory results. The reasons are various. First the structures, the aorta, conus, pulmonary artery, &c., far from being in the same plane are echeloned the one behind the other to a considerable depth, this means that not only are they with difficulty reduced to a flat plan, but also that the extent to which they are exposed is conditioned by the amount of time and patience at the observer's command, as these factors control the care and extent of his dissections. Secondly, it is, above others, the area where the view is likely to be obscured by blood. It is therefore with some diffidence that the following figures are given: in 24 out of 60 cases the conus alone was seen, while in 36 from a fraction to 3 cm. of the pulmonary artery was seen.

Between the upper extremities of the left border of the heart and of the right border lie the great vessels, the ascending aorta on the left (average width, 3.1 cm.) and the superior vena cava on the right (average width, 1.75 cm.).

#### SHAPE OF THE HEART SILHOUETTE

Having described in detail the composition of the anterior surface of the heart and its margins, the next point is the actual shape of the heart as a whole. It was soon obvious that so great was the variation in shape, quite apart from size, that to adopt any stereotyped silhouette was impossible. After several abortive attempts the following plan was adopted. A return was made to the post-mortem reports and those cases were noted in which not only was the heart stated to have been normal and free from disease, but where there was also an absence of any other disease in any way liable to affect its size, shape, or position. Thirty such cases were found and their diagrams copied on to stout paper and then cut out so as to make 30 silhouettes. With these cards a sort of "patience" was played and it was found that with one exception, to be noted later, every diagram could be allocated to one or other of three suits. A composite drawing was then made of all the hearts of each type, and the outer and inner lines of these drawings were arbitrarily taken as representing the maximum and minimum normals—that is, in the investigations of the remaining 48 diagrams only those were accepted as normal whose outline fell between these arbitrary limits. In making these composite diagrams nothing was sacred except the perpendicular—i.e., a silhouette

could be moved up or down or from side to side so as to get the greatest possible agreement between it and the diagrams already drawn in, but the inclination of the heart to the horizontal was most carefully preserved. Fig. 1 shows a typical composite diagram.

The next step was to compare the remaining 48 diagrams with these normals, the same method, that of cutting a silhouette, being used. In this way 19 more diagrams were allocated to their various types. There remained 31 diagrams which could not with justice be assigned to any of the three types, but of which 18 formed a definite fourth type of their own. Thirteen diagrams remained which, either from gross deformity or more usually from enlargement, could not be assigned to any of the four types. As reference to the post-mortem reports showed that they were from conditions such as chronic bronchitis, uræmia, and hypertension, they were discarded without compunction.

There were now four distinct types of normal heart diagram and a single exception, derived from 55 separate cases. They are as follows:—

**Type I. *Inclined heart.***—This in the main is the normal heart of the anatomy books except that the rotation from the left to right already remarked upon is absent. This is the largest class accounting for 28 diagrams (just over 50 per cent.) (Fig. 2.)

**Type II. *Horizontal heart.***—This type is somewhat similar to the former and so not unlike the conventional heart. The decreased angle, however, between the long axis and the horizontal, marks it out as a type of its own. Nine diagrams (about 16 per cent.) were of this type. (Fig. 3.)

**Type III. *Globular heart.***—These diagrams are quite unlike the conventional heart, the absence of any apex being most striking. There were 9 (16 per cent.) diagrams of this type, and it is of interest that the subjects were predominantly male, 6 to 1, and that the average age, 48, is the lowest of any type. (Fig. 4.)

**Type IV. *Square or "conus" type.***—This is the type that grew from the rejected diagrams. Not one of the original 30 normals is of this type, but, as it consists of 18 diagrams (33 per cent.), it must be accepted as a fairly common type, even though abnormal. It is noticeable that the average age is increased by 48 per cent. and the superficial area of the diagrams by 14 per cent. on the other types. (Fig. 5.)

Fig. 6 shows the diagram obtained from the heart of a healthy male of 37 who died almost instantly from a fractured base. It is unique in my experience but being healthy and from a healthy subject must be put on record.

The Table gives average figures as to age, sex, superficial area, &c., from normal hearts of the first three types and the 10 smallest hearts of the fourth type.

*Average figures for the four types of heart.*

	Type I.	Type II.	Type III.	Type IV.
Age in years .. .. .	52	50	48	64
Sex (Male .. .. .)	7	2	6	8
(Female .. .. .)	9	4	1	3
Superficial area (sq. cm.) ..	92.9	90.3	93.5	107.7
Longitudinal axis (cm.) .. .	14.9	13.5	13.3	15.2
Inclination of axis .. .. .	37°	32°	42°	33°
Right perpendicular (cm.) ..	2.3	3.2	3.25	3.7
Left (cm.) .. .. .	10.4	8.9	8.0	9.4
Width of aorta, first part (cm.) ..	2.5	3.1	2.6	3.7
" superior vena cava (cm.)	1.5	1.9	1.4	1.9

I should particularly like to acknowledge my thanks to Dr. John Parkinson who first put the idea of this investigation into my head and who by his encouragement kept it there.

## SOME EXPERIENCES IN GALL-STONE SURGERY

By E. R. FLINT, F.R.C.S. Eng.

SURGEON TO THE GENERAL INFIRMARY AT LEEDS

THE general principles which govern surgical procedure in cholelithiasis are based on experience gained in the treatment of a very common disorder. From the enormous amount of material certain conclusions emerge:—

1. Cholecystectomy is a more satisfactory operation than cholecystostomy in that a higher proportion receive ultimate complete relief from symptoms. The definite risk of stones re-forming after the latter operation does not obtain in the former. In performing cholecystectomy nothing should be clamped or cut until it has been clearly identified.

2. After the gall-bladder has been removed a drainage-tube should be inserted across the site, reaching to the front of the kidney.

3. The common duct should be carefully palpated, and if there is any doubt about its contents it should be opened, explored, and drained to the surface.

4. If there should be a stone in the common duct it should be removed, together with all debris both above and below the opening made in the supraduodenal part, a probe should be passed with certainty into the duodenum, and the duct drained through the opening. In those cases in which the stone is wedged immovably in the lower end it is better to remove it transduodenally than to make prolonged efforts to extract it from above.

5. Operation for stone should not be begun in the presence of deep or increasing jaundice. If for any reason waiting seems inadvisable the minimum operative manipulation that ensures free drainage of the bile should suffice.

These are principles that, if not universally held, certainly guide the conduct of the great majority of surgeons. Those to which criticism might be directed are the third and the fifth. As regards the former, it has been said that the smallest stones can be palpated without opening the common duct. My sense of touch is certainly not sufficiently acute for this; on several occasions I have found a stone after opening the duct, when I had felt reasonably sure none was present on palpation. It is particularly difficult to palpate when the pancreas is hard and nodular, as it is very often when there is cholelithiasis. That other surgeons have the same difficulty is supported by the fact that during six years there were at the Leeds General Infirmary 33 autopsies after cholecystectomy in which there had been no operation on the common duct, and in 6 there were stones found in the common duct, presumably undiscovered and certainly left at operation.

Small stones probably often pass through the duct, causing little or no obstruction, and doubt about the necessity of draining the duct should arise not only because of the uncertainty of the presence of a stone, but also on account of the state of the duct with regard to infection. For this reason the duct should be inspected as well as palpated after dividing the peritoneum covering it. If it is found dilated or thickened, having lost its normal bluish appearance, it should be drained whether a stone can be felt or not. A dilated duct associated with infection indicates the necessity for drainage owing to the possibility of widespread injury to the liver, as in the following patient.

CASE 1.—Female, aged 59. She had had for a long time many attacks of cholecystitis, with tenderness over the gall-bladder accompanied by shivering and jaundice. She was admitted in a critical condition and died the

next day without operation. The post-mortem revealed a slightly enlarged gall-bladder containing mucus and three faceted stones, one of which was impacted in the neck. There was no stone in the dilated common duct, but some muddy bile; the pancreas was distinctly fibrotic. The liver showed a thickened capsule with grossly distorted surface, and on section there was extensive fibrosis enclosing small islets of intensely bile-stained fat with some liver tissue surviving in widely separated areas.

### THE SIGNIFICANCE OF JAUNDICE

As regards the fifth principle some amendment is necessary. There is no question that a patient is much safer for operation when jaundice is absent. It is also a fact that jaundice due to obstruction of the common duct by stone usually begins to wane after a period of waiting, and in my experience this is generally a week or less. The greater risk is attributed to post-operative hæmorrhage; in a sense this is true. I do not think, however, it is the jaundice itself that is responsible for this enhanced tendency to bleed, but some derangement of the liver, of which jaundice is a visible indication. My experience leads me to believe that jaundice as such is not of any great moment, though very useful from a practical point of view in helping to assess roughly the state of the liver, which improves as the jaundice goes and steadily gets worse the longer it lasts. If this is true the wording of principle 5 should read, "Operation for stone in the common duct with jaundice should not be delayed beyond the few days necessary to improve the patient's general condition. If during this period jaundice lessens there is no immediate hurry to proceed with surgical measures; if, however, it persists or deepens the minimum operation that ensures drainage of the common duct should be undertaken at once, and the period of delay should rarely, if ever, exceed a week." In this series of 54 cases of stone in the common duct all the deaths occurred in those patients who were jaundiced at the time of operation, and in which it had been present for over a week; in only one was there any noticeable degree of hæmorrhage. The following is an instance of what I think was faulty judgment, in that delay was too prolonged:—

CASE 2.—Female, aged 63. For three years she had had attacks suggesting biliary colic, and 14 days before admission she became jaundiced. This steadily increased, and on admission was very deep. The diagnosis was clearly obstructive jaundice due to a stone in the common duct, and operation was delayed for a further 14 days in the hope that it would diminish. It remained, however, as deep as ever, and the patient vomited altered blood on several occasions. At operation the gall-bladder which contained several stones was drained and also the common duct which contained a large stone and much debris. She died three days later, passing into a lethargic and comatose state with rising pulse-rate and subnormal temperature. A limited post-mortem was performed; there was no undue hæmorrhage, but a section of liver showed on microscopic examination advanced necrosis with collections of polymorphs.

The condition of the liver has an important bearing on the prognosis of cholelithiasis. Unfortunately there is no method of determining its functional capacity with any degree of accuracy, but I think we may take it as established that in all such cases there is some hepatic injury. This was first pointed out by Graham<sup>1</sup> and later by me.<sup>2</sup> The lesion is a round-celled infiltration surrounding the smaller bile-ducts with or without fatty areas and fibrosis; it extends to both lobes of the liver. Similar changes may be seen in any case of chronic infection in the abdomen, but they are always most pronounced in those with cholangitis, especially of long duration.

It is generally appreciated that the latter, which clinically proclaim themselves by rigors, temperature, quickened pulse, and dry tongue, with or without jaundice, are poorer surgical risks than those that apparently have cholelithiasis alone. It may be possible in some of these to demonstrate by tests that the liver is not functioning normally in certain directions, but we are in the dark about the extent of the injury in any particular patient, and indeed there may be very extensive injury without any of these symptoms. I can recall the case of a woman who, apart from slight jaundice on one or two occasions, had had no evidence of any common duct trouble and was apparently a very good risk, and yet at operation I found a soft stone in her common duct which was distended with dirty bile smelling strongly of *Bacillus coli*, and she nearly died within the first week after operation presenting the symptoms that we are accustomed to call cholæmia. Incidentally she recovered under treatment with continuous glucose-saline given by the intravenous drip method, and I think this was the direct cause of her recovery.

#### PRE-OPERATIVE PREPARATION

We should regard any patient with gall-stones as deserving very careful pre-operative supervision, and do all that is possible to ensure that the defences are put into the best possible trim, though it may sometimes seem superfluous. To the above-mentioned principles should be added, then, pre-operative preparation, which our experience has shown to be beneficial and which may be rather prolonged (subject to the reservations given under principle 5). Since paying particular attention to this matter my mortality figures have come down to 2.5 per cent. in 157 cholecystectomies and 4.3 per cent. in 68 choledochotomies, in 225 cases operated on in the last four years; of these, 123 cholecystectomies were for stone, with 3 deaths, a mortality of 2.4 per cent., and 54 choledochotomies were for stone, with 3 deaths, a mortality of 5.5 per cent. Some four years ago a collective investigation of choledochotomy for stone reported at the meeting of the Association of Surgeons of Great Britain and Ireland showed a mortality of 14.65 per cent. in 621 cases; I attribute my improved results almost entirely to careful pre-operative preparation.

Most of this treatment is not peculiar to gall-stone cases, but generally speaking I think that these patients require rather more care in this respect than those in the general run of abdominal work; this is particularly so when there is any suspicion of infection in the common duct.

The lines upon which pre-operative treatment of my patients is conducted was published in THE LANCET<sup>3</sup>; there has been little change except in the matter of pre-operative medication in preparation for spinal anaesthesia, which I now use in most of my gall-stone cases. With the exception of those who are, or recently have been, much jaundiced, they receive 3 grains of Nembutal by mouth 30-45 minutes before operation. The subsequent spinal anaesthesia makes the operation easier for the surgeon owing to the complete muscular relaxation, and the patient has less flatulence and sickness in the post-operative period. With the technique I use now, combined with Icoral immediately before the spinal injection, the heavy fall in blood pressure, which is an alarming feature of spinal anaesthesia, is seldom seen.

#### ANÆSTHESIA

There does not seem to be a great difference between the mortality with ether and that with spinal anaesthesia;

in this series there were 129 of the former with a mortality of 3.8 per cent., and 96 of the latter with a mortality of 2 per cent., but there may be more in it than appears at first sight, because I prefer a spinal anaesthetic to ether in the patients who are considered the more serious risk for two reasons. First, ether is a cell poison and upsets the biochemical properties of the blood; it causes hyperglycæmia and dehydrates the patient, thereby altering acid-base balance. Prolonged administration also exhausts the thyro-adrenal mechanism and possibly promotes pulmonary congestion and œdema. In the poor-risk patient most of these biochemical states have already been adversely affected. Secondly, though the one serious objection in the past to spinal anaesthesia has been the serious fall in blood pressure that threatens peripheral circulation for a short time, and in seriously ill patients this is undoubtedly a dangerous affair, this fall can be eliminated or kept within reasonable bounds by a proper technique—indeed the pressure may be higher at the end than at the beginning of the operation—and I have seen no ill-effects at the time or afterwards, except occasional transient headache, which can be quickly overcome by the recumbent posture.

#### DIFFICULTIES IN DIAGNOSIS

Gall-stones in the common duct associated with jaundice rarely give rise to any serious difficulty in diagnosis; pain of a characteristic type almost always appears in the history; occasionally, however, it is entirely absent. But difficulty does arise in the obstructive kind of jaundice due to supposed malignant disease of the head of the pancreas.

The following two cases were so alike that a similar pathology was expected, but actually it was very different:—

CASE 3.—Male, aged 45. Except for malaria in 1909 and occasional slight attacks since, he had had no illnesses until he began to be jaundiced about Christmas, 1934, this gradually deepened, unaccompanied by pain at any time; it was of the obstructive type with bile in the urine, clay-coloured stools, and a van den Bergh reaction prompt direct strongly positive, and indirect positive. The blood-sugar was normal; Wassermann reaction negative; excess of unabsorbed split fat in stools, neutral fat normal. He had worked in chemical factories, coming in contact with aniline compounds and nitrobenzene. In the three months between Christmas and operation he had lost 3 st. in weight. The liver was found to be much enlarged; the gall-bladder was not definitely felt. Urine was normal apart from the presence of bile. Phenol-tetra-iodophthalein 2.5 g. injected intravenously showed a 50 per cent. retention after  $\frac{1}{2}$  hour.

Operation, March 4th, 1935, for carcinoma of the head of the pancreas. No obstruction was found; common duct was opened and drained. He died nine days later, gradually fading out without any hyperpyrexia.

Post-mortem: A deeply jaundiced patient; gall-bladder small, thick-walled, and contracted; no stones. No fibrosis or malignant disease of the pancreas. Liver 47 oz.; cut section showed deeply bile-stained swollen short bands of liver cells with rather indefinite edges and areas suggesting recent granulations. Nothing else noted beyond some hypostatic congestion of the lungs. Reported as subacute yellow atrophy.

CASE 4.—Male, aged 60. No history of any note until three months before admission, when he had an attack of diarrhœa and vomiting, which was followed in two to three weeks by jaundice; this gradually deepened, unaccompanied by pain, but with gradual loss of weight. On admission he was of a dark yellow-green colour, and had lost 2 st. in weight; the jaundice was of the obstructive type; he felt reasonably well and was getting about. The liver was much enlarged and the gall-bladder was palpable.

Operation, Dec. 7th, 1935: A small carcinomatous lump as large as a hazel-nut was found arising in the ampulla of Vater and projecting into the duodenum; it was excised. The patient died five days later in a similar way to Case 3.

Post-mortem: The operation area was satisfactory. The liver was congested and the capsule thickened; there was some cirrhosis in the centre of the liver lobules. The most prominent feature seen on section was biliary stasis in the form of inspissated plugs of bile within the epithelial cells and in the fine intercellular canaliculi in the centre of the lobules; the Kupffer cells contained similar pigment. There was fibrous thickening in the portal tracts and polymorphic infiltration.

In both cases operation was undertaken to relieve intractable itching, the patients being anxious that something should be done to ameliorate this, and in the confident belief that the jaundice would prove to be due to obstruction of the common duct by carcinoma of the head of the pancreas.

Gall-stones in the common duct unaccompanied by jaundice may be difficult to diagnose correctly; something like 20 per cent. of cases never produce jaundice. Usually it is possible to be confident the patient has stones, but it may come as a surprise to find one or more in the common duct. I have had one case in which there were 35 stones in the common duct and yet there had never been visible jaundice or other indication that the common duct had become involved. This case shows not only the necessity for investigating the common duct when there is no apparent reason to expect any pathological lesion in it, but also the tolerance of this duct to stones which are not causing definite obstruction or infection. Nevertheless, the sooner stones in this situation are removed the better. But what are we to say of those cases with deep jaundice in which we feel confident there is no stone? Should we recommend operation in spite of the very definite risk, or let things alone thinking the patient has not long to live in any case? On the one hand we know that the majority of these patients will be found to have carcinoma of the head of the pancreas, many of whom will fade out a few days after operation, though most will live a few months longer and in reasonable comfort, the anastomosis causing disappearance of jaundice and with it the often intolerable itching, and promoting a return of good spirits and hope as the visible evidence of illness disappears. On the other hand, a few can be completely cured or relieved for a relatively long time. In this category come the unusual cases of stone without pain, chronic pancreatitis (which even at operation may be indistinguishable from growth), a removable carcinoma of the ampulla of Vater, and other rare tumours sometimes of a simple nature. It is chiefly the possibility of unexpectedly finding one of the conditions in the last group that should determine us to give the patient his chance, as it is frequently impossible to be sure beforehand of the nature of his pathological lesion. It is also something in favour of operation that it can bring ease, mental and physical, in very distressing circumstances. I think, therefore, we should take our courage in our hands and operate on all these cases if the patient's condition, after careful preparation, gives a reasonable chance of surviving the operation.

It is not often one will be faced with such a case as No. 3; nevertheless the possibility should be kept in mind, as this patient had passed through the hands of a consulting physician who was convinced that the condition was carcinoma of the head of the pancreas; in the circumstances it was inevitable that operation hurried the patient's demise.

My experience convinces me of the great value of glucose as a pre- and post-operative measure; in what way it acts is not quite clear. It is a good and easily utilised food and this may be its chief merit, though it is said to have a specific action in protecting the liver against further damage. I am doubtful whether it does so in any other way than providing easily assimilated food for the liver, as it does in the tissues generally. For jaundiced patients particularly it is beneficial, and, given as a continuous intravenous drip, it resuscitates in a remarkable manner those patients who after operation look like passing out in a so-called cholæmic state.

As a complication following operation for stone, duodenal fistula is fortunately rare; I have had only one such case, the circumstances of which were as follows:—

CASE 5.—Female, aged 62. She had had repeated attacks of typical biliary colic with jaundice; there was none at the time of operation and she was considered a good risk. At operation a large stone could be felt in the common duct, which was buried behind the duodenum, the latter being hitched up and very firmly adherent in the region of the hilum of the liver to what was apparently an almost completely destroyed gall-bladder. I think there had certainly been a fistula at some time. In order to expose the common duct it was necessary to free the duodenum, and in doing so it was accidentally opened. The stone was removed from a dilated and highly infected duct, which was drained. The duodenum was closed. Some four days later food and very excoriating fluid came through the wound (probably the drainage-tube had fretted through the suture line) and the patient wasted rapidly. Jejunostomy was done, and after a stormy convalescence the patient made an excellent recovery, the tube being removed from the jejunum in about four weeks.

#### ACUTE DISEASE

As regards the treatment of acute gall-bladder conditions, there is considerable divergence of opinion. Probably most surgeons adhere to the time-honoured practice of delay, awaiting the quiescent period which, as a rule, may be safely expected. When there is pus, following a local perforation, or widespread peritonitis, which is rarely seen, immediate operation is rightly performed; but most of the acute gall-bladder trouble is due to impaction of a stone, usually a single cholesterol stone, in the neck of the gall-bladder, and generally in patients of the younger type. My practice is to treat these cases on similar lines to what one does in acute appendicitis—that is to say, remove the gall-bladder at once if the patient is seen within 48 hours of the onset, and delay operation if the patient comes under observation after this period. The reasons for this are: (1) The patients are generally comparatively young and in reasonably good condition, and operation within 48 hours of onset will anticipate, in some cases, local perforation. (2) Removal of a gall-bladder obstructed by a single cholesterol stone will also prevent a great deal of subsequent trouble because it eliminates pus in the gall-bladder, mucocele, secondary stones, perhaps indigestion due to the diminished and possibly persistent cholecystitis, and also the threat to the liver. (3) If the patient is seen after 48 hours, operation is very apt to disseminate the localised mischief during the following two or three weeks with the result that spreading peritonitis, or severe infection of the wound, may arise, facilitated by the large incision through a great deal of fat and the necessarily extensive manipulations, which may be exceedingly difficult.

These risks introduced by operation are, in my opinion, not justified when experience shows that

there is little danger in waiting, since infection generally remains limited in extent and soon dies out or becomes reasonably attenuated.

## PREVENTION OF DISEASE BY DIET

By A. G. MORISON, M.D. Aberd., D.P.H.

S. DATTA, M.D. Brist.

AND

A. F. WATERS

(From the City of Bristol Public Hospital Services)

In the human experiment, in which the difficulty of full control is notorious, the postulates for the proof of a theory based upon highly controlled laboratory experiment are not often all present in an easily recognised form. This, however, has not prevented considerable gain from coming to mankind out of scientific research.

More than a decade ago McCarrison found that he could keep monkeys from the jungles of Madras healthy or make them ill according to the diet he gave them. In particular, he found that the interaction of faulty food, faulty nutrition, and microbial or toxic agents led to the spontaneous appearance of many diseases or to their controlled appearance according to his desire.<sup>1</sup>

"Public interest has been aroused in this 'newer knowledge of nutrition' as it has been called. The centre of interest is passing from the research laboratory to the application in everyday life of the results of the researches."<sup>2</sup>

The following record of some happenings may be of interest at the present time. In an effort to apply a few of the newer facts of nutrition, some observations which may be pertinent and of significance have been made by the way.

Stapleton Institution is a hospital of 952 beds, functioning as a place for the reception and care of the mentally defective. In 1932 there was an outbreak of dysentery among the inmates (average occupation then 752). On August 21st the first case of dysentery occurred; within forty-eight hours the illness was present in 10 of the 20 wards, and by ten days' time 17 of the wards had become affected. All ages were represented amongst the patients attacked, there being a preponderance of those infirm and elderly, the female proportion being the larger. All this happened in spite of isolation from the commencement of any clinical evidence of intestinal upset, the routine attention to food handling, the wearing of rubber gloves by the nurses on

attending to patients, and the strictest attention to such-like usual details.

Bacteriologically, the first cases presented a *Some* infection, but examination of later cases revealed the presence of Flexner dysentery bacilli, type z. Rigid search failed to reveal any of the usual factors acting as a vehicle for the spread of pathogenic germs. The milk-supply was considered, the farm visited, illness amongst the workers searched for, and the milk itself examined bacteriologically—all with completely negative results. Contamination of the water-supply was also excluded. Of course, such possibilities, on the face of it, seemed to be unlikely explanations of the occurrence, for not one of the resident staff (115) were ill, and further, there was no spread of the illness beyond the institution.

"Green and Mellanby (1930) have pointed out how wide is the margin between the doses of vitamin A which will just maintain a rat in life, if it is not attacked by infection, and the dose which will wholly prevent those infections. The latter dose is about four times as great as the former. Animals receiving doses between these maximum and minimum amounts, while showing no overt symptoms of vitamin-A deficiency, yet suffer from a partial or latent deficiency and are proportionately liable to infection in consequence. This example serves to show that a latent deficiency disease is a real thing and not an imaginary concept."<sup>3</sup>

The limitation of this illness at Stapleton to the patients was considered probably significant, and the dietary was examined according to the criticisms suggested by the Advisory Committee on Nutrition.<sup>4</sup> The protective foods found to be in the diet were as follows:—

- (a) *Milk*.—0·56 pints daily per man value;  
Butter 5·25 lb. in the institution per week (margarine 1·27 oz. daily per man value);  
Cheese 1·27 oz. daily per man value.
- (b) *Vegetables*.—Cabbage, twice weekly; onions, once weekly; carrots, once weekly; parsnips, twice weekly; swedes, twice weekly; fresh fruits, absent; fresh salads, absent.
- (c) *Liver*.—Absent.
- (d) *Fish*.—8·2 oz. weekly per man value (large fish—cod, hake, &c.).
- (e) *Eggs*.—0·514 of an egg weekly per man value.

The diet, then, was deficient in the protective foods (although the total calorie supplies as well as the proportion of first-class protein were quite adequate, allowing, in fact, the recommendation of their slight curtailment). For, the consumption of milk was small; there was not a daily supply of fresh fruit, or of fresh vegetables as salads; the margarine was devoid of vitamin; liver was absent, as were also the fat fishes and fish roes; and eggs were but poorly given.

The following recommendations were adopted by the hospital committee:—

- (1) The addition of 6 oz. (minimum) milk daily per patient.
- (2) The introduction of liver once a week as a "meat" dish (herrings or fish roes alternatives).

Incidence of typhoid and dysentery in the institution.

(3) The introduction of fresh fruits (e.g., oranges) or fresh vegetables (e.g., tomatoes) or fresh salads daily according to season.

(4) The margarine to be vitaminised.

(5) The reduction of 8 oz. meat weekly per man value.

In 1918 there were 47 cases of typhoid fever amongst the patients, and during no year afterwards until 1930 was the disease absent from the hospital. In 1930, 22 cases of dysentery occurred, in 1931 35 cases, while in 1932 the epidemic embraced 123 cases. The incidence of typhoid and dysentery illnesses during the period 1918–May, 1936, is depicted in the accompanying Chart.

It is to be noted that since September, 1932, there have been only 3 cases of enteric fever at the institution, while dysentery has been absent. We are not aware of a change in any factor in the life or environment of this community which can be pointed to as likely to have affected the incidence or spread of the intestinal infections amongst its members, unless the considerable changes in the dietary immediately introduced at the cessation of the outbreak in August–September, 1932, be such a factor.

It is frankly admitted that these observations at this institution have been over only a very short period, but observation will continue at this and other institutions where a change in the dietary has been made having in mind the same criticisms.<sup>4</sup> The facts are now recorded because they may represent an application in everyday life of the results of the researches into this "newer knowledge of nutrition."

## CONGENITAL URETHRAL OBSTRUCTION

By ANNE E. SOMERFORD, M.D. Manch., D.P.H.

PATHOLOGIST, ROYAL MANCHESTER CHILDREN'S HOSPITAL  
AND MANCHESTER SKIN HOSPITAL

THOUGH it is common knowledge that congenital urethral obstruction may be unsuspected until autopsy, yet usually, according to Young, Frontz, and Baldwin (*Jour. of Urol.*, 1919, iii., 289), there are obvious symptoms. These include incontinence alternating with retention of urine, a distended abdomen, and evidence of renal destruction and infection, such as œdema, anæmia, anorexia, diarrhœa, vomiting, and loss of weight.

In the case under consideration the patient was a boy 11 years of age, who died from uræmia a few days after tonsillectomy. The history elicited after death from the mother by Mr. K. H. Watkins (to whom I am grateful for the use of the notes) was as follows. He passed a lot of urine which was sometimes frothy but never blood-stained. He did not have any incontinence, dysuria, or retention, though a large amount was passed during the morning and his diurnal frequency was probably greater than that of other boys. The bowels were usually loose.

At autopsy the following conditions were found. The body generally was well nourished. The brain was congested but was otherwise normal. The

bladder was much enlarged and almost filled the lower half of the abdomen: it contained semi-purulent urine. The wall was somewhat, but not

FIG. 1.—The kidneys, ureters and bladder.

FIG. 2.—Dissection of the urethra. The black line points to the enlarged verumontanum.

much, hypertrophied. The ureteral orifices were patent, and it was obvious that there could have been no obstruction to the flow of urine through them. There was double hydro-ureter and hydro-nephrosis (Fig. 1), and sections of the kidneys showed thin shells of tissue with but little remaining kidney structure. As far as could be made out there was no obstruction in the urethra except that caused by a hypertrophied verumontanum (Fig. 2). There were no valves, folds, or diaphragms such as are usually found in obstructions of the posterior urethra.

As cases of congenital hypertrophy of the verumontanum are not common, and the symptoms were so vague and so few, this case seemed worth recording.

## POSITION OF THE URETERS IN A CASE OF PROCIDENTIA

By J. LEON JONA, D.Sc., M.S. Adelaide,  
M.D. Melb., F.R.A.C.S., M.C.O.G.

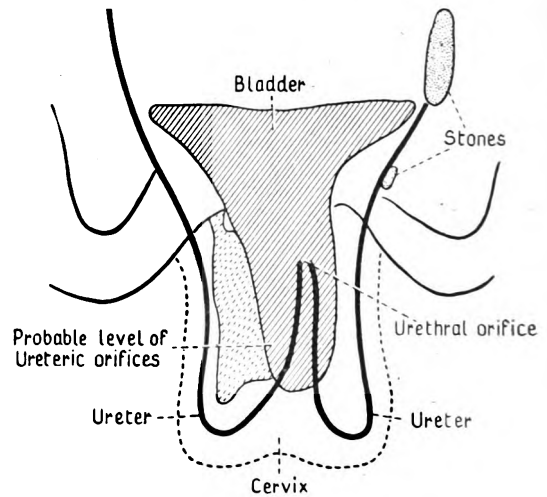

HON. ASSISTANT SURGEON TO THE WOMEN'S HOSPITAL,  
MELBOURNE

THE accompanying radiogram and tracing show the position that the ureters occupied in a case of procidentia; they actually lay outside the body along the antero-lateral aspects of the cervix. The coiled-up catheters can be seen in the bladder, and the base of the bladder, attached to the upper part of the cervix, is well down in the vagina if not actually also outside the body. The catheters in the bladder can also be seen passing upwards to the urethral orifice and so to the outside world.

The picture suggests an interesting point. One could hardly imagine the ureters and bladder "migrating" down the cervix, the alternative

suggestion being that the "hypertrophy" of the cervix has taken place in its upper part in relation to the base of the bladder which, with the ureters,

the ureters attached to these parts of the cervix or adjacent tissue. The pictures certainly suggest that before operating in a case of procidentia a skiagram

Radiogram and tracing showing position of ureteric catheters.

has been carried down in relation to this part of the cervix. One can imagine that the loops in the ureter are due to increased growth of the lateral parts of the cervix; hence the more pronounced descent of

should be taken of the ureters, either with opaque in-lying catheters or by intravenous pyelo-ureterography. It would be interesting to know the findings in a large series of cases investigated in this way.

## SUBPHRENIC ABSCESS

BY WALTER BROADBENT, M.D. Camb.,  
F.R.C.P. Lond.

CONSULTING PHYSICIAN TO THE ROYAL SUSSEX COUNTY  
HOSPITAL, BRIGHTON

SUBPHRENIC abscesses often present difficulties in diagnosis, which are illustrated by the following cases.

CASE 1.—A man, aged 52, had a sudden acute attack of pain in the right epigastrium, which spread to the right under the lower ribs. He did not vomit. When he was seen by a doctor two hours later the pain was acute, the temperature 100° F., and friction was audible for about 4 inches above the right lower rib margin in front. A diagnosis of pleurisy was made. Next day the pain was much less, the temperature 102° F.; the friction had gone and the breath sounds at the right base were diminished.

During the week the man became steadily more ill, his tongue dry and brown, and his temperature 99° in the morning and 102° to 103° at night. Dullness had progressed up to above the angle of the right scapula. A needle had been inserted, but no fluid was found. When I first saw him this dullness was marked but, on deep inspiration, weak breath sounds could be heard almost down to the base, with fine crepitations. In front there was diminished resonance in the right third and fourth spaces, but from the fifth space down to the rib margin resonance was tympanitic. On tapping one coin on another a bell note could be heard from the fifth rib down to 1 inch above the umbilical level in the right nipple line. This bell note area narrowed up to the ensiform cartilage, but widened towards the axilla. Breath sounds, which were fair in the upper chest, ceased suddenly where the tympanitic area began. The heart was pushed upwards and outwards, the apex being in the fourth space 1½ inches outside the nipple line. This was evidently a subphrenic gas-containing abscess, and a needle inserted

in the anterior axillary line in the eighth space let out foul gas and thin foetid pus. Later a portion of rib near the costal margin was removed, and a large abscess opened. A hard irregular ridge could then be felt across the right side of the abdomen above the umbilical level. Unfortunately the man died and no post-mortem was allowed, but the ridge must have been adherent omentum and colon forming the lower limit of the abscess.

In this case the origin of the trouble was, almost certainly, a perforated duodenal ulcer with a slow leak, not sufficient to cause vomiting. In similar cases the gall-bladder and also the falciform ligament become glued by peritonitis to the duodenum and colon, and the colon to the abdominal wall, a channel being formed with the gall-bladder and falciform ligament on either side and the liver and colon above and below, up which the duodenal contents spread round the margin of the liver on to the surface of the right lobe, and form a subphrenic gas-containing abscess.

The friction, which led to the erroneous diagnosis of pleurisy, was really hepatic friction, caused by the diaphragm rubbing on the inflamed upper surface of the liver. Hepatic friction may also be heard in the early stage of a perforated gastric ulcer near the pylorus, and in some cases of cholecystitis; also in cancer of the liver. In cholecystitis and cancer the friction may be heard under the abdominal wall some way below the costal margin.

CASE 2.—The second patient was sent into hospital with a diagnosis of query empyema, needles having been put into the back of the left chest in four different places without result. The man looked very ill and had been running a hectic temperature for a couple of weeks. The lower half of the back of the left chest was dull, breath sounds were absent in the lower 3 inches. In front there was resonance of a tympanitic character below the

fourth rib, and the heart's apex was 1 inch outside the nipple line in the fourth space. On the right side liver dullness was normal external to the vertical nipple line, but internal to this from the fourth rib downwards there was a tympanic area. On percussing over this with two coins a loud bell note could be heard with the stethoscope, and the same bell note could be heard as far as the left anterior axillary line, and down almost to the umbilical level. On rolling the man over on to his right side most of this tympanic area to the right of the sternum was replaced by the absolute dullness of fluid. This sign and the absence of abdominal movement in respiration are important in differentiating the condition from an abnormally dilated stomach. A needle passed into the tympanic area drew off gas and foul-smelling pus. A tube put in just below the left costal margin led to a slow recovery.

This subphrenic abscess must have been caused by the slow leak of a gastric ulcer, which had caused pain but not vomiting. Such abscesses are limited below by adhesions of the great omentum and the front of the stomach to the abdominal wall, and to the left by the spleen and the gastro-splenic omentum. On the right they are bounded by the falciform liga-

ment of the liver which, as the abscess enlarges, is pushed very much to the right of its normal position. At operation I think that it is safer to just drain the abscess, and not to make any attempt to find the gastric ulcer.

When a subphrenic abscess forms without gas the diagnosis is more difficult. The upper abdomen does not move with respiration on the side affected, while it still usually moves on the other side, giving the curious effect of a slight bulge on the sound side in inspiration. If on the left side abnormal dullness may help, but the abscess is usually far back. Then there is tenderness and resistance on deep palpation, and the lower part of the left lung is dull and silent from pressure collapse. If on the right side, it may be a sequel to a ruptured appendix or to a perforated gastric or duodenal ulcer which has been stitched up. The weight of the liver seems to squeeze these abscesses forward, so that they present in front. Liver dullness in the chest becomes duller and rises higher, and breath sounds disappear. A needle should be inserted in front in the sixth space in the dullest and most silent spot.

## MEDICAL SOCIETIES

### ASSOCIATION OF CLINICAL PATHOLOGISTS

THE summer meeting of this association was held in the rooms of the York Medical Society, Stonegate, York, on June 13th. Dr. S. GOODMAN PLATTS (York) occupied the chair.

Mr. E. J. KING, D.Sc. (London), spoke on

#### Phosphatase and Liver Function

The discovery of the enzyme phosphatase, he pointed out, followed the work of Harden on yeast fermentation of sugar, of which he found the formation of phosphoric esters to be an essential stage. Robison found a mechanism in yeast capable of breaking up these phosphoric esters and depositing the phosphate as inorganic calcium salt. This suggested that a similar mechanism might be responsible for deposition of bone salts. The enzyme was shown to be present in hypertrophying and absent in non-ossifying cartilage. Its presence in embryonic bone coincided with the appearance of areas of bone-salt deposition. It was present in rather more than normal amount in rachitic bones. The presence of the enzyme was soon detected in blood, and Kay and Roberts independently found large concentrations of phosphatase in the blood of patients suffering from osteitis deformans, osteitis fibrosa cystica, osteomalacia, and rickets. Later it was discovered that it was also high in other clinical conditions—notably in obstructive jaundice. Dr. King described experiments performed by himself in collaboration with Armstrong and Harris which were designed to throw light on the relationship of the increase in blood phosphatase to disturbance of liver function. Obstruction of the common bile-duct was found invariably to lead to a rise in blood phosphatase. On relief of the obstruction the blood phosphatase fell. The same thing had been demonstrated on human subjects suffering from biliary obstruction and relieved by operation. Previous attempts to estimate the phosphatase activity of bile had failed owing to the fact that bile contains substances which precipitate phospho-molybdic acid, rendering the colorimetric estimation of free phosphate

impossible. With the use of phenyl-phosphate as a substrate, and the substitution of a determination of the phenol instead of the phosphate liberated it was possible to estimate bile phosphatase. The daily excretion of phosphatase in the bile of dogs was followed; great variations were observed, but it became evident that large quantities of the enzyme are constantly being excreted by the liver through this channel. The significance of this constant passage of phosphatase into the intestine with the bile was not clear. There was some reason to believe that the enzyme is concerned in the absorption from the gut of both glucose and fat. It seemed likely that the phosphatase of the blood plasma arises in the bones, and is excreted by the liver into the intestine by way of the bile. Any interference with its normal excretion, such as is encountered in obstructive jaundice, thus results in an elevated level of the enzyme in the blood. Experimental toxic jaundice was produced in dogs by means of chloroform, phosphorus, and toluylene-diamine, and was always followed by an increase of the blood phosphatase. Hæmolytic jaundice was produced by phenylhydrazine; the red cells were grossly reduced in numbers and much bilirubin appeared in the urine, but the blood phosphatase showed no increase. In conclusion Dr. King stated that plasma phosphatase is seldom or never elevated in hæmolytic jaundice. Toxic and infective conditions show moderate increases. Very high phosphatase values occur strikingly in obstructive jaundice alone, and may be diagnostic of this condition.

Dr. F. S. FOWWEATHER (Leeds) offered observations on the

#### Van den Bergh Reaction

The questions most frequently asked of the clinical pathologist in reference to a case of jaundice were, he said: (1) is there an increase in the bile-pigment in the blood, and (2) of what type is jaundice when present? The van den Bergh reaction made a fairly accurate reply to the first question; to the second its response was not so definite. Difficulties arose when there was a mixture of toxic and obstructive jaundice and this was made even worse when hæmolytic icterus was also present. It was doubtful if

the van den Bergh reaction was of prompt direct type in every case of obstructive jaundice and never so in non-obstructive jaundice. McGowan considered that the type of reaction depended on the alkali reserve of the blood and Snider and Reinhold had claimed that it depended on the concentration of the bilirubin. Dr. Fowweather was not inclined to admit either of these explanations as fully satisfactory, though both had elements of truth. Azo dyes were indicators and were influenced by pH; the colour given by the reaction therefore varied with the alkali reserve of the serum used. This variation of colour had led to considerable confusion in the interpretation of so-called "biphasic" reactions. This term should be reserved for those in which some colour develops immediately but only reaches its maximum after a long period. Dr. Fowweather described experiments by means of which he had been able to isolate two separate salts of bilirubin, one giving in solution an indirect and one a direct van den Bergh reaction. The second salt was unstable and reverted readily to the indirectly reacting type. He believed that bilirubin was capable of existing in more than one form, each capable of forming its own salts. Bilirubin capable of giving the delayed reaction existed in the more stable form which Dr. Fowweather called A; in the less stable form B it gave rise to the prompt reaction met with in obstructive jaundice. Variations in the alkali reserve had an influence on the stability of the B form tending to convert it to the A. In regard to the nature of the colour change in the van den Bergh reaction Dr. Fowweather suggested that it was probably due to the fact that bilirubin had the general structure of a butadiene; on coupling with a diazo compound azo derivatives were produced. In view of his conclusions Dr. Fowweather anticipated little further improvement in the diagnostic accuracy of the van den Bergh reaction.

Dr. ALAN MONCRIEFF (London) spoke of

#### Jaundice in Children

He pointed out that the incidence and degree of physiological jaundice in the new-born varied in different clinics and also with the season of the year, being commoner in cold weather. The degree of icterus bore no direct relationship to the amount of bilirubin in the serum, this being due apparently to a variation in the power of the capillary endothelium to hold the pigment back. The polycythaemia of the foetus depended upon the reduced oxygen tension experienced in intra-uterine life and the bilirubinæmia of the new-born depended upon the reduction of the polycythaemia. Icterus gravis seemed to depend upon a failure of the balance between the red cell-destroying and red cell-regenerating functions. It had been attributed both to a primary defect of the erythron and to a primary defect in erythroclasis; probably elements of both entered into the case. The persistence of nucleated red cells in large numbers established the differential diagnosis as between icterus gravis and physiological jaundice. The only effective treatment for the condition was the parenteral administration of whole blood. Dr. Moncrieff pointed out the close relationship between sepsis and jaundice in young children; this was apparently due to the fact that the balance between blood formation and destruction remained unstable and easily upset for some time after birth. Speaking of jaundice in older children Dr. Moncrieff drew attention to the occurrence of cases of illness without visible icterus in children in close contact with others suffering from so-called

catarrhal jaundice. He suggested that certain cases of this malady might show no jaundice, probably due to failure of the bilirubin to pass the capillary endothelium. He described one case which satisfied the hæmatological criteria of acholuric hæmolytic jaundice but failed to show any icterus.

Dr. H. E. COLLIER (Birmingham) spoke of

#### "Lead Action"

as a clinical entity and as a problem in clinical pathology. By "lead action" he meant the often unrecognised degree of slight lead poisoning which precedes the appearance of the classical symptoms and signs of plumbism and which were constantly to be observed among lead workers. The earlier clinical features were pallor, lassitude, and slight dyspnoea on exertion. The earliest laboratory findings consisted of the appearance of basophil stippling of the red cells, without at first any gross diminution in their number; there was also an increased excretion of lead in the urine and faeces and hæmatoporphyrin might appear in the urine. The later clinical effects of "lead action" were premature senility, a tendency to diseases of the heart, blood-vessels, and kidneys, and a lessened expectation of life. In the later stages of lead action basophil stippling of the red cells might be absent; it could, however, usually be made to appear by methods aimed at de-leading such as the exhibition of parathormone or ammonium chloride. Dr. Collier drew attention to the large amount of disability produced by minor degrees of "lead action" and uttered a plea for the frequent and intelligent examination of the blood of those exposed to the risk of lead poisoning.

#### Demonstration

Dr. KING and Mr. G. A. D. HASLEWOOD, D.Sc. (London), demonstrated improvements in the van den Bergh technique. They pointed out that gross inaccuracies exist in the quantitative determination as ordinarily carried out. These were due (1) to the use of an artificial standard of incorrect strength, (2) to an improper allowance being made for the volume relationships in the test, and (3) to the frequent inability to get an accurate match of diazotised sera against any of the artificial standards. The proper strength of the cobalt sulphate standard should be 1.9 g. per 100 c.cm. instead of the commonly used 2.16 g. A constant volume of 4 c.cm. of coloured liquid can be got in the test by the use of 1 c.cm. of serum, 0.5 c.cm. of diazo reagent, 3 c.cm. of absolute alcohol, and 0.5 c.cm. of saturated ammonium sulphate. The difficulty of matching the colours was eliminated by the use of a green glass filter (Ilford spectral green).

Dr. S. C. DYKE (Wolverhampton) demonstrated specimens of adenomatosis of the liver associated with a gross splenomegaly. The condition occurred in an undeveloped female, actual age 24 but apparent age about 12, who was also suffering from chronic renal disease.

---

BIRMINGHAM UNITED HOSPITAL.—Dr. Stanley Barnes has resigned from the office of honorary physician to this hospital owing to his increasing duties as dean of the medical school and as a member of the executive board of the Hospitals Centre. He has been appointed honorary physician to the neurological department, and Dr. T. L. Hardy will succeed him in the charge of a medical unit. Mr. W. S. Adams has been appointed surgeon to the throat and ear department.

## REVIEWS AND NOTICES OF BOOKS

**Symptoms and Signs in Clinical Medicine**

*An Introduction to Medical Diagnosis.* By E. NOBLE CHAMBERLAIN, M.D., M.Sc., M.R.C.P., Lecturer in Medicine, University of Liverpool; Assistant Physician, Royal Infirmary, Liverpool. With a chapter on the *Examination of Sick Children* by NORMAN B. CAPON, M.D., F.R.C.P., Lecturer in Diseases of Children in the University. Bristol: John Wright and Sons, Ltd.; London: Simpkin Marshall Ltd. 1936. Pp. 424. 25s.

DURING the student's first months in medical wards he is confronted with a confusing mass of new ideas and new phenomena. He has to acquire the technique of history-taking and physical examination *pari passu* with the principles and the facts of medicine, at the bedsides of patients who come in to hospital because they are ill rather than for the benefit of his education, and with the help of teachers who are apt to forget the limitations of his experience and outlook. An introductory text-book can help him greatly to see order in this new world and to make orderly progress in familiarising himself with it. The book must of course be clear, sound, and thorough, but not cluttered with detail. A description of methods alone is dry; the meaning of the signs and symptoms elicited, and an indication of the disease processes that produce them, are necessary to make them intelligible, but the balance in the book between medicine and method, if we may so express it, must be deftly adjusted. The bedside and test-room methods demand first place and most space, but the more elaborate laboratory and radiological procedures must be mentioned and their purposes indicated, for the student should learn from his first encounter with a patient that a full diagnosis is achieved only by assessing and piecing together all the facts of a case.

Dr. Chamberlain's book meets these considerations really very well. He writes easily and succinctly, he seems to have the good teacher's power to put himself in imagination into the mind of his pupil, and his outlook is fresh and up to date. His illustrations are unusually numerous and apt, though some of the coloured ones are not entirely successful. It is to be hoped that in later editions he may need to borrow even less from older text-books. We should like to see a more physiological discussion of renal insufficiency, which he does not distinguish from renal disease, and a fuller consideration of intermittent claudication and the signs and symptoms of peripheral arterial disease than appears in his one-page section on Trophoneuroses. A few words are inaccurately used: "anthropoid" does not mean ape-like, and "symptom," though properly defined on page 1, is sometimes used elsewhere in place of "sign." But these are minor matters.

The book is well printed and produced, and it deserves a welcome in other medical schools as well as in that from which it comes.

**Die Einheimische Sprue und Ihre Folgekrankheiten**

*Sekundäre Avitaminosen.* By Prof. Dr. K. HANSEN and Dr. H. v. STAA. Leipzig: Georg Thieme. 1936. Pp. 113. M.7.80.

DURING the preceding six months the authors encountered four cases of non-tropical sprue in Germany and one in which the diagnosis was doubtful. They

were sufficiently impressed to write a monograph of 113 pages on the subject, 30 of which are devoted to the case-histories. The value of these case records is limited by the paucity of biochemical data in the cases studied. The first patient, a woman aged 52 years, suffered from rickets as a child, developed gastro-intestinal symptoms 42 years later, and subsequently pigmentation and tetany. Campolon injections (2 c.cm. daily) were followed by a specific reticulocytosis of 8.7 per cent. on the seventh day following injection. A notable feature was the presence of thrombocytosis with a tendency to vascular thrombosis. The pelvis was deformed as in osteomalacia, and osteoporosis was widespread. The adrenals showed a striking abundance of lipoids in the cortex and large nodular islands of cells containing lipoids and resembling adenoma. The second case, occurring in a man of 59, was of considerable interest as it began as a pernicious anæmia with typical blood picture and glossitis. Later, features of subacute combined degeneration of the cord appeared. Diarrhœa with light fatty stools did not occur until three months before death. Autopsy showed subacute combined degeneration of the cord and an absence of hæmosiderosis from the liver. The third patient, a woman of 32, gave a history of four years fatty diarrhœa, megalocytic anæmia, osteomalacia, tetany, nutritional changes in the nails, and pigmentation of the skin. Muscular atrophy and hæmorrhagic diathesis associated with thrombocytopenia developed. Vitamin D given parenterally did not relieve the condition. The fourth patient, a man of 53, was the sole survivor of the series. He gave a history of diarrhœa associated with greyish-yellow fatty stools, osteoporosis, hypochromic anæmia, bleeding gums, and skin hæmorrhages.

The authors are in agreement with Thaysen that celiac disease presents no essential differences from idiopathic steatorrhœa or non-tropical sprue other than those due to age variation. The latter disease in turn is identified with tropical sprue. The anomaly that three out of four of their cases were dead within six months, whereas patients with tropical sprue returning to Europe generally recover, was not commented on—an omission no doubt attributable to the fact, stated in the text, that the authors had had no opportunity of studying tropical sprue.

**The Cerebro-spinal Fluid and its Relation to the Blood**

*A Physiological and Clinical Study.* By SOLOMON KATZENELBOGEN, M.D., Associate in Psychiatry in charge of the Laboratory of Internal Medicine, Henry Phipps Psychiatric Clinic, Johns Hopkins Medical School. Baltimore: The Johns Hopkins Press; London: Humphrey Milford, Oxford University Press. Pp. 468. 22s.

THIS book is a critical review of recent work on the chemistry of the cerebro-spinal fluid and its relation to blood chemistry. The size of the task which the author set himself may be judged from the 40-page bibliography; and the text shows that this is not a mere collection of references, but that each of the articles has been carefully examined. Most of the work deals with the barrier between blood and cerebro-spinal fluid considered as a physiological mechanism. How far the Donnan membrane theory can be applied to the formation of the cerebro-

spinal fluid and how far the process of dialysis is modified by vital forces is a question on which controversy still rages. On the one side there are the adherents of Lina Stern who see in her "hæmato-encephalic" barrier a mechanism with as delicate a poise as an endocrine gland, while on the other side there are those who hold with F. K. Walter that the permeability of the barrier rises and falls equally in respect to all substances, whether these are normally present in the blood or given in test doses. It is unfortunate that workers in these two camps have held their views so strongly that much of their recent work has been polemical rather than scientific. Dr. Katzenelbogen was brought up in Stern's school, and his sympathies naturally tend towards her views, but the review which he has made of the subject is so thorough and critical that the reader should be able to form his own verdict.

The most disappointing chapters are those on chlorides and glucose. The author makes little attempt to explain the very constant level at which the chlorides are held in the cerebro-spinal fluid, nor is his analysis of the recorded observations sufficiently detailed to give the reader a basis on which to form his own conclusions. As regards glucose, much confusion has been introduced by the inclusion of data arrived at by the use of out-of-date and unreliable methods. In fact so few reliable data are available as to the relationship between blood-sugar and cerebro-spinal fluid sugar that most of this chapter should have been omitted. For example, most of the reports of abnormally high percentages of glucose in epidemic encephalitis are worthless as the methods used at that time gave constantly higher results than Mestrezat's method, on which the normal was based. Indeed recent work has only served to show that Mestrezat's estimate of the normal as 55 to 65 mg. per cent. is remarkably correct for all patients with normal blood-sugar levels.

Taken on the whole this is a very able and unprejudiced review of the present state of knowledge of the chemistry of the cerebro-spinal fluid. The omissions are due either to the method of presentation or to the rudimentary state of knowledge on certain aspects of the subject.

### Chemistry of Natural Products related to Phenanthrene

Monograph Series No. 70. By L. F. FIESER, Associate Professor of Chemistry, Harvard University. New York: Reinhold Publishing Corporation; London: Chapman and Hall Ltd. 1936. Pp. 358. 32s. 6d.

This is a most valuable work and one that ought to be at hand in the biochemical and medical library. Every physiologist and every pharmacologist realises the important part that the phenanthrene nucleus has begun to play in physiological and pharmacological rôles. This knowledge has developed entirely during the last ten years. The compounds of phenanthrene were formerly regarded as being of interest only in organic chemistry, but to-day we know that this nucleus is contained in such important physiological substances as the bile acids, the sterols, vitamin D and possibly E, the sex hormones, the cardiac "glucides" derived from the strophanthus plant, and digitalis, to mention only a few of the more important substances.

This book deals with the chemical relationship of these compounds and presents a very full review of literature. The physiological and pharmacological

sections of the book are equally good. It is of interest that its appearance coincides with that of a German monograph, "Über sterine Gallensäuren und verwandte Naturstoffe," by Dr. Hans Lettré and Dr. H. H. Inhoffen. These two books taken together give the reader a view of the present position of sterol chemistry and its application to pharmacology and physiology such as can rarely be obtained by the reading of monographs.

### L'année médicale pratique

By Various Authors. Published under the direction of Dr. CAMILLE LIAN, Professor of the Medical Faculty of the Tenon Hospital. Paris: René Lépine. 1936. Pp. 796. Fr.26.

THE reader gets the impression from this Annual that, though much of the matter here reported may be of an ephemeral nature, French medicine is in a healthily adventurous condition, always willing to try new things. For example, André Trèves and G. Vidal-Naquet describe a method of treating arthritis deformans of the hip-joint by drilling a hole through to the centre of the head of the femur; and J. Périssin, a method of treating causalgia by acetylcholine injections. There is a note on evipan as a general anaesthetic, and a useful article on fractures of the calcaneum. Among many other interesting matters dealt with are the treatment of barbiturate coma, the occurrence of asthma as a sequel to healed pulmonary tuberculosis, the surgery of the diaphragm, and the treatment of cardiac insufficiency by total thyroidectomy. Vratislav Jonas strongly advocates X rays as the treatment of choice in Cushing's syndrome. The rival merits of the lumbar and sub-occipital routes for meningeal puncture are discussed by J. Périssin, and the treatment of intractable chronic prostatitis by intraprostatic injection of vaccines by F. Marsan. A method of treating hay-fever by the injection of sclerosing solutions into the base of the inferior turbinate has, perhaps, a topical interest. The appendix includes lists of recent drugs, books, and instruments, and alphabetical indices both of the editions of the last five years and also of the present edition.

## REPORTS AND ANALYSES

ERGO HEALTH BREAD—STARCH REDUCED  
(POLLEY & CO., LTD., 44/54, PLYMOUTH-ROAD, LONDON, E.16)

THE box contained a number of ordinary-sized rolls each weighing slightly less than  $\frac{1}{2}$  oz. They were very light and bulky in texture. When analysed the following results were obtained:—

	Per cent.
Water .. .. .	8.30
Fat .. .. .	1.27
Ash .. .. .	0.94
Protein .. .. .	37.70
Crude fibre .. .. .	24.00
Altered starch (carbohydrates) .. .. .	27.79

These figures show that "Ergo" bread contains nearly four times as much protein as ordinary white bread. The carbohydrate content (starch altered by cooking) is correspondingly low, and the crude fibre higher than in white bread. The claims of the makers are thus substantiated. The product being attractive in appearance and palatable should be appreciated by those who are concerned in devising suitable dietaries for patients suffering from disorders of metabolism.

# THE LANCET

LONDON: SATURDAY, JUNE 27, 1936

## THE COMMON COLD AND INFLUENZA

It is some five or six years since DOCHEZ and his colleagues in America produced evidence that the common cold has a filtrable virus as its prime cause. Not only was it shown that colds could be produced experimentally in the chimpanzee and human volunteers by means of filtered nasopharyngeal washings, but it was stated that this virus could be cultivated in a tissue medium consisting of minced chick embryo and a special broth in which a high reduction potential was maintained by cysteine hydrochloride and a vaseline seal. Quite special interest was attracted by this last claim since the conditions of cultivation were unlike what had been found essential for the growth of other viruses. Colds were produced in human volunteers by means of culture virus, but failure was recorded when the experimental animal was the chimpanzee. When DOCHEZ's cultures were tested on human volunteers in this country by ANDREWES and OAKLEY entirely negative results were obtained. A recent paper by DOCHEZ, MILLS, and KNEELAND,<sup>1</sup> however, confirms and extends their earlier work. Several strains of cold virus have been isolated and maintained in artificial culture. The conditions of cultivation have been the same as before and colds have been produced experimentally in human volunteers with strains which had reached the eighty-eighth subculture; later subcultures proved avirulent. It was noted that the virulence of the cultures was best maintained when subcultivation was carried out at intervals of 2-3 days; when longer intervals were used, up to 9 days, the percentage of colds produced experimentally with the cultures fell considerably. Other interesting points concerning the virus of the common cold are recorded in this paper. The virus in filtered nasopharyngeal washings can be conserved in an active state for at least 13 days if cysteine is added and the washings stored in the cold, and it has been shown that the virus can be preserved in a dry form. But the main interest of this communication is the reiteration of the claim to have grown the virus by this unusual method.

The same number of the *Journal of Experimental Medicine* contains a second paper by this team of workers which recounts their experience with influenzal virus. Here again human volunteers were their experimental animal and it is claimed that both with filtered nasopharyngeal washings and cultures made by the same method which they used for the virus of the common cold, success attended their attempt at experimental infection.

<sup>1</sup> Dochez, A. R., Mills, K. C., and Kneeland, Y.: *Jour. Exper. Med.*, 1936, lxiil., 559.

The surprising thing is not perhaps that infections were produced, but that these infections, with one exception, took the form of the common cold. Thirty-nine volunteers in all were infected either with filtered nasopharyngeal washings or with cultures, yet in only one was the resulting infection clinical influenza. DOCHEZ's reputation as a research worker will ensure for this work the most serious consideration, but certain facts make it impossible to accept the findings unreservedly. Clinical experience tells us that neither the common cold nor influenza confers a solid immunity, but there is nevertheless a difference between the two, for the immunity conferred by an attack of the latter disease is definitely more durable. It might be, of course, that this difference was merely due to the degree with which the hosts' tissues were implicated, the virus of the two diseases being the same. But against this must be placed the failure of the Hampstead workers to transmit the common cold to the ferret, whereas the virus of epidemic influenza infects this animal readily. It is somewhat surprising that DOCHEZ and his colleagues did not make use of the ferret in their investigations and also that they did not test the neutralising power of an anti-influenza serum on their virus. The susceptibility of the ferret to the virus of epidemic influenza has been abundantly demonstrated and strains isolated from epidemics in different parts of the world seem to be the same; so that had one known how these strains of virus obtained by DOCHEZ from influenza behaved towards the ferret, one would have been in a better position to judge of their work.

The failure to infect ferrets with filtered nasopharyngeal washings from cases of so-called sporadic influenza recorded by ANDREWES, LAIDLAW, and SMITH<sup>2</sup> suggests that sporadic cases labelled influenza may not have the same ætiology as epidemic influenza. Sporadic influenza may even comprise a number of different conditions. Might it not be that DOCHEZ and his team were not working with true influenza? The fact that most of the patients from which they obtained their virus were sporadic cases occurring in inter-epidemic periods lends weight to this view. And this is further strengthened by the observation of MAGILL and FRANCIS<sup>3</sup> that the cultural requirements of the virus of epidemic influenza are the same as those of other viruses, no growth occurring in a tissue medium if reduced oxygenation is maintained by cysteine and a vaseline seal.

## FOCAL INFECTION

No one who has worked on the ætiology of a straightforward infective disease is likely to underrate the difficulties of a valid demonstration that a disease is due to a given micro-organism, even when the effects of the micro-organism are highly characteristic. There are, for example, some awkward gaps still left in the demonstration that scarlet fever is due entirely to the action of

<sup>2</sup> Andrewes, C. H., Laidlaw, P. P., and Smith, W.: *Brit. Jour. Exper. Path.*, 1935, xvi., 566.

<sup>3</sup> Magill, T. R., and Francis, T.: *Jour. Exper. Med.*, 1936, xliii., 803.

the hæmolytic streptococcus, though undoubtedly those who accept this view are in a much stronger position than their opponents. When we seek for the explanation of such a disease as rheumatoid arthritis we are, however, in worse case, and to meet the difficulty the focal infectionist often steps in where the more orthodox pathologist fears to tread. Focal infection of the mouth or tonsils is commonly invoked as the cause of rheumatoid arthritis, but the difficulty immediately arises that most people are sooner or later subject to infection of these parts, and the onus remains of explaining why so many escape arthritic manifestations. If streptococci are the cause of rheumatoid arthritis, why are they so seldom isolated from the joints? Why, again, are the lesions of rheumatoid arthritis so different from those known, on good evidence, to be associated with the actual presence and multiplication of streptococci in the joints? When driven so far, the adherent of the focal infection doctrine must seek refuge in some indirect explanation such as "allergical reaction" or the action of "endotoxin." With the help of either of these additional assumptions it becomes possible to explain why a disease is so unlike what we should expect from our knowledge of its prime cause. Few subjects in medicine have been the excuse for so much loose thinking as that which goes under the name of allergy. In spite of the wide popularity of the allergy theory most immunologists look upon it as vague and unprofitable, or at least they define it so in such a way as to deprive it of any general application. It is perhaps not realised that the idea of endotoxin is equally vague, and indeed, as H. ZINSSER has shown in a brilliant review,<sup>1</sup> no adequate proof has been provided that endotoxins as generally understood have any concrete existence. Much weight is commonly laid on the apparent cures of a general disease which take place after the removal of a local focus of infection. Alternatively, weight is laid on the fact that interference with a focus—e.g., by removing it—may apparently make the disease worse. Such observations can perforce only be made on isolated cases, and controls, admittedly difficult to obtain, are practically never provided.

The doctrine of focal infection has drawn much support from E. C. ROSENOW'S experiments on the elective localisation of bacteria, particularly of the streptococci. He maintains that strains of streptococci from human appendicitis tend to localise in the appendix when injected into experimental animals, that strains from arthritics tend to localise in the joints, and so forth. Unfortunately others have failed to confirm ROSENOW'S experiments, and most bacteriologists remain unconvinced by his attractive theory. W. L. HOLMAN, from a study of the literature,<sup>2</sup> concludes that the bacteriology of focal infection seems to be that of the streptococci; Dr. W. P. MURPHY, in an address published elsewhere in this issue, states that the mouth is the most important site

of focal infection. The streptococci of the mouth may then be looked upon as the crux of the doctrine. C. C. OKELL and S. D. ELLIOTT have recently shown<sup>3</sup> how easily mouth streptococci may under certain circumstances reach the circulatory blood. These observers were endeavouring to fill in some gaps in the ætiology of subacute bacterial endocarditis, and they refrained from applying their findings to the general theory of focal infection. Even with the knowledge that *S. viridans* frequently reaches the blood stream we are brought little nearer to an explanation of most of the diseases which have so far been attributed to focal sepsis. In presenting their case the adherents of the focal infection theory have failed so far to provide statistical data for valid inference, or to satisfy KOCH'S postulates. The doctrine may well have some useful applications in pathology, but its uncritical acceptance will not carry us safely very far. Whether or not certain blood diseases are to be ascribed to septic foci, as suggested many years ago by W. HUNTER, again more recently by P. C. GIBSON,<sup>4</sup> and now by MURPHY, must be decided on the strict laws of evidence.

#### CENTENARY OF LONDON UNIVERSITY

IN the autumn of 1836 KING WILLIAM IV. granted to the University of London the right "to hold forth to all classes and denominations of our faithful subjects, without any distinction whatsoever, an encouragement for pursuing a regular and liberal course of education." To what extent this remarkable phrase in its Charter has been put into practice will no doubt appear in the centenary celebration next week. The breadth of learning which has been aimed at is typified in the selection of those who are to receive honorary degrees from the University at its centenary. The development of a federal university is difficult, and in the absence of any central building to impress on public imagination the extent, repute, and power of its university the people of London have been slow to become aware of what a university ought to mean. Next week will afford the opportunity for a fuller realisation. It may be instructive to recall some of the incidents that led up to the granting of the Charter a hundred years ago as set out in our own columns. Writing on Saturday, Nov. 28th, 1835, Mr. WAKLEY remarked:

"Within a very few years the fact of the metropolis of England not having become an University, under the sanction of an Act of Parliament, or the authority of some royal decree, up to close of the year 1835, will be considered one of the most extraordinary circumstances that can be related in connection with the history of the literature of this country. It does not even appear that, until a very recent period, the question of establishing an University in the metropolis has ever been mooted by persons whose character could give weight to their suggestions. When the project was first announced for founding the University which is now proceeding in its successful career in the northern part of London, the projectors were made the objects of contemptuous

<sup>1</sup> Jour. of Immun., 1920, v., 265.

<sup>2</sup> Arch. Path. and Lab. Med., 1928, v., 68.

<sup>3</sup> THE LANCET, 1935, ii., 869.

<sup>4</sup> Ibid., 1936, i., 994.

ribaldry. . . . The opponents of the measure resorted to every species of slander which malignancy could invent, in order to deter the subscribers from proceeding in the great national work in which they had engaged. It was pretended, indeed, that the idea of founding an University in London, or, rather, of establishing colleges in London, which should confer on the metropolis itself the title of 'an University,' had originated in a desire to offer an opposition to the national Universities of Oxford and Cambridge. . . .

"The founders of the University were stimulated by no such unworthy motive. . . . They were not so vain or so foolish as to attempt to enter into a contest with the ancient Universities of Oxford and Cambridge, immovably fixed as were the latter on solid masses of treasure, and renowned as they had become throughout the world as the most celebrated establishments of learning in civilized Europe. There was no desire to circumscribe the sphere of advantages attaching to a collegiate education, which had been created by those venerated seats of learning. On the contrary, the promoters of the great academic enterprise in London sought to widen that sphere, to multiply the opportunities of learning, and to afford to some thousands of the youthful inhabitants of England the means of acquiring, on cheap and accessible terms, a first-rate education in literature and the sciences. The friends of Oxford and Cambridge, therefore, had no legitimate ground of suspicion or jealousy on that occasion, and it is quite certain that the gentlemen connected with the ancient universities, who are the most exalted from the extent of their learning, and command the greatest share of respect for those qualities which most distinguish at once the philosopher and the man, became at an early period the advocates of the new scheme, and ardently did they desire that the efforts of its supporters might be crowned with success. Without having received the slightest assistance from the Parliament or the Crown, the claims of the University of London to distinction have taken a firm hold on public opinion, and, under difficulties which it may be considered are now surmounted, the institution has passed through a seven years' ordeal, preparatory, we trust, to running a splendid career of national usefulness.

"Under circumstances of so favourable a character, we do not expect the proprietors . . . will approve of any measure which can lead to an inference with the thinking portion of the community that the interests of the University could be advanced, that its reputation could be increased, or that the sphere of its usefulness could be enlarged, by obtaining from the Legislature or the Crown any privileges of a strictly exclusive or local nature. . . . The principle of exclusiveness cannot exist, certainly it cannot flourish, in the new metropolitan institution. London itself must become a regularly-organized and acknowledged University in the British Empire, and the great establishment now styled the University of London will, we are convinced, throughout many succeeding ages, take the lead under the name of 'University College,' or some other title, as the most liberal of those academic establishments, by means of which the fame of the University of the British capital will be mainly sustained. It will constitute at once the chief pillar and the brightest ornament of the metropolitan universities, and the names of its founders will be placed by the future historians of the literature of England amongst those of the chief benefactors of the human race."

A hundred years after these words were written it is recorded, in the Principal's report for 1935-36, that admissions from all sources to the university during the previous year numbered 10,000; that candidates for all examinations amounted to 44,000, of whom 19,000 were successful; and that some 4000 degrees and diplomas were gained. The "great establishment now styled the Univer-

sity of London" has seven university departments, 36 incorporated colleges and schools, and 24 institutions with recognised teachers. The senior academic staff responsible for the organisation of the teaching includes more than 250 professors and 140 readers. The story of this vast expansion from humble beginnings will doubtless be told at the forthcoming celebrations of which a summarised programme appears on another page. It is a source of gratification that of all the faculties none bears a higher reputation than that of medicine and that in this centenary year it is a distinguished member of our profession who occupies the post of vice-chancellor.

## BIRTHDAY HONOURS

THE viscountcy conferred on Lord DAWSON will give peculiar pleasure to the profession of which he is a well-loved member. His personal services to three sovereigns and his standing as elder statesman are common knowledge; the influence of the Royal College of Physicians has been extended during his presidency, now in its sixth year; but known to comparatively few is the extent to which his kindly wisdom has remained at the disposal of younger men who have constantly to remind themselves that he is not of their generation, so youthful is his outlook. Congratulations are due also to Sir RICHARD CRUISE, surgeon oculist to the KING, who becomes G.C.V.O., and to Surgeon Vice-Admiral R. W. B. HALL and Dr. ARTHUR MACNALT, each the medical chief of an important national service, and to the nine knights-bachelor among whom Mr. A. E. WEBB-JOHNSON is the best known in this country for his signal services in re-creating the Middlesex Hospital. Apart from the other honours recorded on p. 1496 there are some recipients not medically qualified whose work has furthered medical progress. Lord WAKEFIELD, a benefactor of hospitals, gets the G.C.V.O., and Sir HERBERT AUSTIN, whose gifts to the University of Cambridge were recently announced, becomes a baron. Lady SUSAN GILMOUR, now D.B.E., has done yeoman service for the Queen's Institute of District Nursing in Scotland. Dr. G. T. MORGAN, F.R.S., is director of chemical research at the Department of Scientific and Industrial Research. To these and to the nurses whose names figure in the list medicine in its widest aspect owes a considerable debt.

---

FRACTURES COMMITTEE OF THE MINISTRY OF HEALTH.—The first meeting of the committee on the rehabilitation of persons injured by accidents, which has been set up by the Home Secretary, the Minister of Health, and the Secretary of State for Scotland, was held on June 18th under the chairmanship of Sir Malcolm Delevingne. It was decided in the first instance to consider arrangements for the treatment of fractures, and information will be collected as to the number of cases of fracture and other injuries by accident, and their local distribution. Films illustrating modern methods of treatment of fractures, and the results obtained in the early restoration of working capacity, were shown to the committee by Mr. Watson Jones of the Liverpool Royal Infirmary, and Mr. Kenneth Pridie of the Bristol Royal Infirmary. The next meeting of the committee will be held in the autumn.

## ANNOTATIONS

## CLINICAL RESEARCH AT CAMBRIDGE

AN important step towards the development of clinical teaching and research at Cambridge has been taken by the general board of the University. The board has recommended the establishment, under the faculty of medicine, of a department of medicine, whose head shall be the regius professor of physic; and the appointment of an assistant director, at a salary of £700 a year, to organise and conduct clinical research at Addenbrooke's Hospital and in the university laboratories. In making these recommendations the board refer to the oft-expressed desire to make better use of the opportunities provided by the hospital for the investigation of disease. Plans for such development have hitherto been frustrated by lack of funds, but an income of not less than £1200 will shortly become available under the Elmore bequest, and full provision can now be made for the stipends of three or four qualified graduates who will undertake research under the direction of the regius professor. "The Elmore bequest," the report continues, "is one reason for the immediate establishment of a laboratory for research in clinical medicine, but another and very important reason is the appointment of Dr. Ryle as regius professor of physic. His two immediate predecessors held their chairs for comparatively short periods and, with only a short prospective tenure at the time of his appointment, neither of them could be expected to develop a school of clinical research in Cambridge. Professor Ryle has many years before him, which he hopes to devote to research, and it is incumbent on the University to provide him with proper facilities. The new arrangements with Addenbrooke's Hospital ... have enabled Professor Ryle to arrange for clinical research to be conducted in the wards and in the out-patients' department of Addenbrooke's Hospital, without additional expense falling on the university or the hospital. These arrangements have the approval of the honorary staff of the hospital, who are willing to put at the disposal of the staff of the proposed department of medicine all the clinical material that is available." Accommodation for laboratory work will be provided by the allocation of certain rooms in the pathological department. Besides the professor the staff will consist of the assistant director and three or four graduates (the Elmore students) who will devote their whole time to clinical observation and research. Members of the visiting staff of the hospital and of its laboratory staff will also join the unit. The establishment of this new department should provide excellent opportunities for collaboration between those engaged upon clinical problems and workers in the other scientific departments of the University. Addenbrooke's Hospital is situated in convenient proximity to the departments of pathology, biochemistry, physiology, and pharmacology.

It is estimated that in addition to the income from the Elmore bequest, £1400 a year will be needed for the payment of the assistant director and the maintenance of the laboratory. Towards this sum the faculty board of medicine have allocated £450 a year from the Sheild Fund, leaving £950 to be provided from the University Education Fund. Although the report of the general board has yet to be approved, applications for the assistant directorship may be addressed to the regius professor at any time before August 1st.

## ADOLF LORENZ ON HIMSELF

A PIONEER in orthopædics born in poverty, Adolf Lorenz<sup>1</sup> was always regarded by his mother as destined to become "ein grosser Herr" through the promise of her brother, the future Abbot Gregory, to have him educated as a choir boy in the great Benedictine monastery of St. Paul, Carinthia. When the boy, at the age of four, clad only in fustian breeches and shirt, found in his father's saddler's shop a single funeral glove, he rushed to his mother saying: "Am I not a real grand gentleman now?" He received the discouraging answer: "But you must have two gloves for that" and spent the rest of his life, he says, in the search for this qualification. Forty-five years later, during one of his numerous visits to the States, he quoted this story; he felt he had found the glove, for he had won the esteem of medical colleagues. In his boyhood, in spite of bare feet, except in mid winter, and a restricted diet, his only ailments were bow-legs and an attack of conjunctivitis; while the cover shows a man looking less than his eighty years, hale and hearty. The choir boy would have become a Benedictine monk and not a doctor, if it had not happened that the Obergymnasium was some distance from his home, and he had to find his own lodgings and earn his keep by tutoring and so tasted the sweets of liberty and of feminine society.

This work is the record of an egoist, but an interesting and versatile one. Lorenz writes in simple language with a sense of dramatic values and a sure instinct for the effective word. His book gives the impression that orthopædics as a specialty started in Vienna about 1890 and there is not the slightest reference to the Italian pioneers or to the Boston workers, while of early visits to Berlin, London, and Paris, the author says: "There was nothing to see or learn." He must have missed Liverpool altogether. He laments the neglect of apparatus by the younger generation of orthopædic surgeons, who are beguiled by the attractions of operative work, a swing of the pendulum back to the day when Lister made open surgery safe. Lorenz recognises the need for scalpel and chisel, but would like them to be the last resort, not the first. He asks to be remembered as a "conservative" surgeon, though he actually achieved fame as a "bloodless" one. He explains that his manipulative methods were forced upon him in early Listerian days because a chronic eczema, induced by the carbolic spray, drove him from operative work, till aseptic technique again put the knife in his hand. The disaster of his youthful career thus benefited thousands of patients.

The book is largely written for that American public which gave the author marvellous welcomes during his extraordinary tours of healing across the States. The first of these resulted from the offer of a two-million dollar fee for the reduction of a congenital hip dislocation in the child of a multi-millionaire—a fee which did not include the prolonged after-care, involving a second visit of the professor to the States and later of the little girl to Vienna. The other visits to America were equally extraordinary because, though the author coöperated with general practitioners, physicians, and lay boards of well-known hospitals, he appears to have ignored entirely the

<sup>1</sup> My Life and Work. By Dr. Adolf Lorenz, Hofrat and Professor of Orthopædic Surgery, University of Vienna. New York and London: Chas. Scribner's Sons. 1936. Pp. 362. 12s. 6d.

band of skilled orthopædic experts who have made famous their centres in Boston, New York, Baltimore, to mention only a few. There is a brief reference to his helpful colleague Albee, and a note that an invitation to the New York Ruptured and Crippled Hospital, given by a physician, was afterwards withdrawn on the representations of other colleagues. It is clear from the author's account of his professional activities that in addition to his technical skill and original ideas it was his personality as a whole which made him so acceptable alike to the poorest parents of cripples and to business magnates in U.S.A., as well as to crowned heads in Europe and to presidents of the United States.

#### THE SIZE AND SHAPE OF THE HEART

In his Lumleian lectures, published in the last two issues of THE LANCET, Dr. John Parkinson gave a masterly account of the variations in shape and size of the heart as revealed by radiography. He described the different forms of silhouette of the normal heart associated with different types of body-build, the abnormal appearances produced by such common deformities as scoliosis, and the deviations from the normal attributable to pathological enlargement of the different chambers of the heart. Incidentally he made it abundantly clear that the information given by the senses of touch and hearing, skilfully combined, on which our fathers in medicine chiefly relied, had been proved to be depressingly unreliable. Seeing is believing, and while the exact significance of shadows thrown by gastric ulcers or duodenal deformity may still be in doubt, the cardiac silhouettes visible under the X rays carry conviction interpreted by the experienced cardiologist with a comparatively small margin of error. Not that radiology can tell the whole truth. A radiogram with the patient facing the screen gives us a nearly perfect picture of what we used to try to map out roughly by percussion. But it is still only a diagram in two dimensions; further information can be obtained by rotating the patient, but even so there is no reliable formula for calculating heart volume, and what we would really like to know is the three-dimensional volume of the heart. As Dr. Parkinson has shown, the greatest contribution which radiology has made to our knowledge of the pathological anatomy of the heart is that the shape of the cardiac silhouette in the different positions enables us to say which chambers of the heart are enlarged.

The more conservative members of the profession may be disturbed by Dr. Parkinson's wholesale condemnation of percussion as a means of estimating the size or shape of the heart, and there is something to be said from this point of view. Admitting that the doctor's coarse thumb and finger often fail to plumb the exact depth and width of the heart, and that radiology can tell us everything which we can learn from percussion with a much greater degree of accuracy, they will contend that it is not, and in the immediate future is not likely to be, available as a routine method for use by the general practitioner. It is certainly incumbent on the clinical teacher to show his students not merely what can be achieved under ideal conditions, but also what they themselves may hope to achieve under the limitations imposed by family practice, where they still have to rely chiefly on their unaided senses. Can we afford entirely to dispense with palpation and percussion? If not we can at least, and this is common ground, teach students the limitations of these methods, and show them, as Dr. Parkinson has done, that the

information they are capable of giving is only a very crude approximation to the truth.

There is another anomaly that has yet to be completely resolved—the fact that both in health and in disease the anatomy of the living heart as revealed by radiography differs considerably from that seen in the post-mortem room. One reason for these differences may well be that the heart of the cadaver is not generally examined *in situ*. In this respect the investigations of Dr. T. Skene Keith reported on p. 1466 of this issue provide an important connecting link between the clinical and post-mortem findings. Dr. Keith is concerned here chiefly with the four normal types of heart silhouette he has been able to make out from a study of some 50 cases. It is rather disappointing that he makes no reference to any cardiac radiograms that may have been taken during the life of this group of cadavers, but he states that in a subsequent paper on the diseased heart it will appear that there is a fair degree of agreement between the outline of the heart as seen at autopsy and that obtained in orthodiagrams or telerradiograms. This is likely to be a study valuable to cardiologists, who will join Dr. Keith in gratitude to Dr. Parkinson who put the idea of this investigation into his head and by encouragement kept it there.

#### DOUBTS ABOUT DRUGS

ALL plants which have been cultivated by man have been profoundly modified from their wild condition. Of late years this has been carried out deliberately and the difference between a Cox's orange pippin and the crab apple or between an exhibition rose and a dog rose of the hedgerows would fill us with astonishment if we were not accustomed to it. These thoughts prompted Mr. Harold Deane's address last Monday afternoon at Bournemouth as chairman of the British Pharmaceutical Conference. Mr. Deane has drugs in his blood, if one may put it that way; his grandfather was the first president of the conference 70 years ago and practised his calling in those ruder ages when the legislature had not as yet been persuaded that the sale of poisons should be allowed only by those who could read and write. In the case of the apple, as in that of the rose, there are easily applied tests of quality; thus the orange pippin tastes better than the crab, and the standard rose is more beautiful to look at, more pleasing to the nose, and more enduring than the dog rose. There are no such simple tests for the properties of cultivated drugs; their medicinal value cannot be judged by their flavour, their appearance, or their colour. Mr. Deane took as an example the cultivated English henbane: "It has," he said, "an altogether different appearance from, and a stronger aroma than, the imported herb. The ordinary pharmacist will say it is a much superior drug, and a tincture made direct from the English drug hardly seems the same preparation as the one made by diluting a liquid extract of the foreign drug. Is there any difference in the medicinal activity? No one really knows." Coming from an eminent pharmacist these observations are a little disquieting. The compilers of the British Pharmacopœia have assumed that the alkaloids are the only thing that matter and have also assumed that these alkaloids are the same after an extract has been evaporated down as they were before; while admitting that these assumptions are "quite likely true," the chairman of the conference says "there is no proof of them." Here, it will be seen, is a twofold doubt: are the medicinal virtues of plants due solely to the

alkaloids and does the extract of a plant evaporated down by heat possess all the virtues of the original drug?

It is a curious fact that the earliest list of drugs in existence, the Ebers Papyrus made in Egypt 4000 years ago, contained a larger number of drugs than does the latest British Pharmacopœia. The total number of drugs known to mankind must run into tens of thousands, yet there are only 63 in the British Pharmacopœia. It has been inferred from this that the vegetable drugs of value are strictly limited in number; it may perhaps be inferred with more justice that there is much research work waiting to be done by bodies like the British Pharmaceutical Conference. Mr. Deane's own view is that there will be a still greater falling off in the use of vegetable drugs and that only such plants as the opium poppy, digitalis, and belladonna, which have active principles with readily determined properties, are likely to remain of importance. He admits, however, that "there are drugs which have properties at present unknown or unproved that may be valuable and research might find them out." Continental opinion favours the view that the day of vegetable *materia medica* has not passed. In many countries vegetable drugs are used more extensively than they are here and several Central European Governments are assisting agriculturists to cultivate them. In Soviet Russia elaborate plans have been made for the cultivation of vegetable drugs, and laboratory work is to be encouraged with the object of sifting the wheat from the chaff in a field which is rank with tares. It is said that man acquired his first knowledge of the value of medicinal plants by observing the ways of animals, and after all these years we still appear to be in doubt whether the dog when he eats the whole herb is not getting the best medicine.

#### THE POOL OF LONDON

Sir Cecil Levita's suggestion in the *Times* to form an airport for London by damming the Thames at Woolwich has drawn from Colonel W. Butler a rejoinder on certain issues of public health. Colonel Butler points out that were the river dammed below London it would, during dry summers when the flow over Teddington Weir is small, become virtually a stagnant pool, its self-purifying powers would thus be reduced, while the adventitious pollution would continue. This is a strong point, although its strength might be obscured for a time by the effect of sedimentation, whereby the mud banks would be concealed and the supernatant water become clear and (possibly) well oxygenated. But sooner or later the mud at the bottom would ferment and the resulting gas, buoying up masses of foul mud, would render the Thames as offensive as was the Lee a few years ago below Tottenham lock. Possibly the water might deteriorate from the beginning of the suppression of tidal motion. There is no doubt that the stirring up of the water of those tidal rivers which from their geographical position must be muddy, by dispersing the lighter (and putrescible) matters of mudbanks, does lead to oxidation of the mud (although it may thereby reduce the dissolved oxygen content of the water) besides accelerating the rate of absorption of oxygen by rapid renewal of the air-water interface. On the other hand the sewage discharged into the Thames above the barrage may be so successfully purified (as is indeed likely so far as West Middlesex is concerned) that the oxidation of accumulated as well as of continuing pollution may go on inoffensively after a time, if not at first.

But even then the pool would become a rich medium for the growth of weeds which, barring the right kind of fauna to keep them within bounds, must impede navigation and themselves become an offence when they rot. Colonel Butler remarks that the rise and fall of the tide displaces the purer air of the river over its banks and conversely draws the stagnating air of the streets into the channel. The volume of air so moved is large—about 50 million cubic yards between London Bridge and Albert Dock. But the movement is spread over some six hours and the atmospheric exchange may be insignificant compared with that due to a breeze or to convection from warm surfaces. The idea of a Thames barrage is not new, although earlier schemes were intended to improve the seaport rather than to provide an airport, and the tidal flow has had earlier apologists. In his presidential address to the civil engineers five years ago Sir Cyril Kirkpatrick said: "The supremacy of London as a port with its approaches from the sea is due to the tidal scour, which should not be impeded."

#### ADJUSTING THE CHILD TO HIS ENVIRONMENT

CHILD guidance clinics usually aim at helping difficult children in two ways: by altering the environment to suit the child's needs, and by direct approach to the child himself. At the Institute of Child Psychology little attention is paid to the former of these two methods. The directors, Dr. Margaret Lowenfeld and Dr. Ethel Dukes, hold the view that none of us can expect to have his environment cut to his own measure throughout life, and that the child's business, therefore, is to learn to fit into his environment. Anyone who has to do with children will appreciate the difficulty of their task. The child's mind is not easily accessible to the Olympians. At the Institute the child is both approached and treated through the medium of play therapy, and a detailed report is written by the worker attending the child on each visit to the clinic. A mass of information has been collected in this way, for treatment may extend over years, so that every child's dossier becomes in time a formidable document. The annual report for 1935 announces that a method of analysing and indexing this valuable psychological material has now been devised, and a system of filing statistical records is already in use. The play therapy rooms are in a sense the most important part of the Institute. Plenty of material is available to occupy hands, wits, and attention. The enuretic boy can, if he will, build a world, and then, Zeus-like, drown it beneath floods from a watering can. The aggressive child can dramatise battle, murder, and sudden death with a patient and consenting adult to abet him. The aim is not only to obtain the disappearance of those symptoms for which the child was referred, but to eradicate the emotional disturbance which lies beneath them. Each child is examined physically at the first visit, and any necessary medical treatment is arranged. Good results are being achieved more easily and quickly as knowledge is gained and mistakes are avoided. All cases discharged are systematically followed up. A three years' training course is open to physicians and psychologists, and a shorter course, of one year, is available for teachers and social science workers. Parents are interviewed on the occasion of their first visit, and a well-placed hint is often of value in changing the parental attitude to the child's peccadilloes. As the report says:

"Though the first aim of treatment is to enable the child to cope even with a difficult environment and

unsatisfactory parents, there is nothing to be lost—and often everything to be gained—by giving the parents an opportunity of helping instead of hindering the child's development."

Mental capacity is assessed, on the child's first visit, by means of the usual mental tests; in addition, the mosaic test, devised at the Institute, is also employed, and is regarded as a test of temperament and emotion. The subject is required to use the mosaic pieces to form a pattern which is pleasing to him, and experience has shown that the designs produced can be classified as fundamental, concrete, abstract, or incoherent; and that the type chosen can be correlated to some extent with temperamental and emotional factors in the subject.

Recently the Institute has published a *News Bulletin* which will appear six times yearly; each issue will contain an article on some topic of interest to those concerned with child psychology, current psychological news, book reviews, and correspondence.

### "AERONEUROSIS"

ON examining 163 unselected aeroplane pilots Captain H. G. Armstrong<sup>1</sup> found that 18 of them (11 per cent.) suffered from a nervous disorder which he calls "aeroneurosis." This is to be diagnosed by "the occurrence of a functional gastric disorder in pilots of several years' experience, combined with a general irritability and increased motor activity with subjective complaints of insomnia and mental fatigue." Prominent among the exciting causes are, first, exposure to the risk of accidents; and, secondly, what Armstrong calls "ego deflation." In his own words, "the World War changed the status of airplane pilots from crazy fools to national heroes . . . gradually however aviation has become more commonplace . . . This slow but definite change has deflated the pilot's ego and thereby created a further emotional stress. There is a constant attempt to regain face, to reclaim and hold a fading dream. . . . The higher the intelligence the more this holds true." He is on safer ground in arguing that prevention is more effective than any particular line of treatment. A careful examination of candidates would probably, he thinks, eliminate the condition, but would have "the distinct disadvantage of depriving aviation of those who are acknowledged to be the highest type pilots. The problem resolves itself into a question of whether it is more desirable to select the better pilots who break down after ten or fifteen years' service or poorer ones who are more durable." Armstrong does not, however, explain how the disorder could be recognised in embryo, nor why it should only be the better pilots that suffer in this way. His paper in fact does not carry full conviction. The nomenclature of psychological medicine is already blamed for being cumbersome and confusing, and a very clear case must be made out before introducing a new disease. The late Graeme Anderson used the term "aeroneurosis" in 1919 but it has never come into currency. And why should it? What is there about the symptoms which do not come under the existing classification of the neuroses? Flying may of course be the "trigger cause" in bringing to light conflicts of an economic, domestic, or instinctive nature. But what occupation may not have the same effect? Even if flying is regarded as an extra load upon a person this is far from proving that the partial breakdown it helps to induce is in any way specific. To base nomenclature upon "trigger causes" is a step in the wrong direction.

### INDUSTRIAL MEDICINE

ON another page Dr. H. H. Bashford describes his unique experience of industrial medicine, for he is chief medical officer to the Post Office which is the largest employer of labour in this country. In many ways, he tells us, the Post Office as an industrial concern differs from other large industries. For instance, all the lower-paid employees receive free medical attention from general practitioners on a capitation basis. This service is of course not compulsory; if they choose to pay for them post-office employees can have their own private or panel doctors, but in any case the local post-office medical officer is responsible for the supervision of the sick absence of the whole staff in the offices to which he is attached. Private certificates must be countersigned by him and panel certificates scrutinised before pay is authorised. This régime has led to another remarkable feature of the post-office medical service; it has complete and accurate sick records under actual working conditions of nearly a quarter of a million men and women aged 16 to 60. In these records there are still unworked mines of information both for industry and medicine. They have already helped, Dr. Bashford tells us, to destroy one or two medical bogies. At first the discovery of albumin in the urine of adolescents was regarded as evidence of the commencement of Bright's disease, until it was found that 1 in 20 of the boys entering post-office service and 1 in 6 of the girls had albuminuria which was really of no serious import. The records too have demonstrated that present-day boys weigh 16 lb. more and are 1½ in. taller than those of the previous generation, the corresponding figures for girls being 10 lb. and 1 in. Not only have these records made medical history, but to some extent also industrial history; for the employees receive full pay when they are absent for illness, and it has been a common criticism outside that this must reflect on the sick rates. Dr. Bashford says "there are undoubtedly some men and women who may take advantage of such a system, but my experience has been that there are relatively not very many." And he adds that although loss of wages may be an incentive to an early return to duty, there is plenty of evidence that it brings the younger men and women back to work too soon. Any move in the direction of an immediate curtailment of pay during sick absence would in his opinion be a retrograde step.

With a few more years of experience to guide them the Industrial Welfare Society have revised their brochure<sup>1</sup> on "Medical Service in Industry." In its present form it is a publication of social importance for it elaborates the influence of industry as a factor in community health. The most important development in the period between the two editions has been the growing realisation that organised economic and industrial functions affect the general health and well-being of the individual, quite apart from specific hazards and risks. Emphasis is laid on the part played by general practitioner and industrial doctor working in harmony, each seeing a different aspect of the patient and each placing his or her experience at the other's service. The idea that industrial medicine is a rival and competitive function to general practice is shown to be false; where a spirit of antagonism exists it is not the conception which is wrong but its interpretation. In this brochure industrial medicine, in its widest sense as a new shoot

<sup>1</sup> Jour. Amer. Med. Assoc., April 18th, 1936, p. 1347.

<sup>1</sup> Issued to member firms only. The address of the society is 14, Hobart-place, London, S.W.1.

on the tree of medical thought and practice, is fairly and accurately presented, though the diversity and complexity of some of the issues are not fully stated. Study of the brochure leaves the impression that a better definition of the work would be the industrial branch of social medicine. There is still, both within and without the medical profession, a failure to realise the larger medical issues resulting from the industrial development of the last twenty years. The Industrial Welfare Society has taken on itself the task of showing that industry has its social duties, not least of which is the need to take a share in preventive medicine. There is welcome evidence that many business firms are taking an interest in the rehabilitation of their employees after injury and we should like to see an analysis of the well-known legal and financial difficulties of treating injured persons with recommendations for their solution founded on the Society's large experience. The chapter on records contains significant data of sickness absenteeism, including an analysis of the 8.4 days lost per year in a staff of 679 women. In another section effort is made to stimulate interest in the medical supervision of the staffs of small firms. Industrial medicine is not the prerogative of large organisations like the Post Office; the problem of the future is the evolution of a practical and comprehensive system for the medical care and supervision of the staffs of the innumerable small concerns. This is bound to come, but it will come quicker with the realisation that new economic and industrial needs call for new measures and that these measures require co-operation between general medicine and the medical problems of a mechanistic economic order. The brochure is issued only to members of the Industrial Welfare Society but the society might do well to make it easily available to the medical profession, and it would be additionally valuable if they would state more fully and explicitly their attitude to the organisation of hospital services. We have an uneasy feeling that these are not always nor everywhere fully in line with modern industrial needs, and nothing would be more valuable than informed, friendly, and constructive criticism.

#### PSYCHOTHERAPY IN GENERAL PRACTICE

"SOME years ago members of the profession were thoroughly hostile to psychotherapy. Now there is an immense appetite for it." Dr. A. C. Court's statement, communicated to a symposium on psychotherapy in general practice arranged by the Medical Society of Individual Psychology on June 11th, reflects an impression which will hardly be disputed. The problem remains how to equip the family doctor with tools which are more effective than his age-old weapons of suggestion, persuasion, and transference; for he has always used a personal influence to straighten out family tangles, and has assumed a fatherly relation to those unable to bear their burdens until they are strong enough to resume them. Now that he is using these methods more consciously and is keen to learn how to use others as skilfully, the question arises how he can best be taught the basis and technique of such psychotherapy as is open to him. Dr. S. Crown, who opened the discussion, suggested the publication of case documents in general medical journals, with analyses of many cases of the particular type of disorder under discussion, of their course and of their treatment; also the organisation of discussions not on general problems but on the results of the psychological investigation of symptoms and diseases. Dr. S. H. Lubner regards as the most important factor an alteration in the attitude of the great teaching hos-

pitals where the medical man derives his technical knowledge. At present, he contends, the teacher is satisfied when the student has differentiated between what is organic and what is "functional," and that a "complete and devastating ignorance of the anatomy and psychopathology of the mental personality is compatible with an honours degree." The student carries this ignorance into general practice where, having rigidly excluded evidence of organic disease, he will fill his record cards with such remarks as "neurasthenic," "nothing wrong," or "swinging the lead," giving the patient tortured by unconscious forces no help in the struggle to escape. Dr. M. Marcus, on the other hand, is less concerned with the student than with the practitioner; he admitted that the wisdom of including psychology in the curriculum of the medical student was open to discussion, but held there should be no question about the absolute necessity of giving the qualified practitioner some knowledge, at least, of its fundamental principles, for without this the practice of medicine became sterile, and divorced from life. Dr. Court, as we have noted above, is more cheerful even about the present position; his thesis is that general practitioners have been doing psychotherapy all the time and doing it well. They will not necessarily be better when more self-conscious, more accomplished; the mysterious qualities which guided them before will continue to be the predominant element in cure. The time has come, however, when the leaders of the profession must guide and control this curiosity now aroused on all sides about mental processes and human behaviour, and as soon as clinical psychology is widely taught it will become an outstanding form of our national method in medicine.

#### VISIT OF FRENCH SURGEONS

THE Royal College of Surgeons of England has made an arrangement with the Académie de Chirurgie of Paris, whereby French surgeons will visit Britain and British surgeons will visit France in alternate years for scientific meetings. The first of these tours will take place in ten days' time, when some 40 French surgeons, led by Dr. Louis Bazy, secretary-general of the Académie, will come to London. On Monday, July 6th, there will be a meeting beginning at 10 A.M. at the College in Lincoln's Inn-fields, when Prof. E. W. Hey Groves will open a discussion on the treatment of fractures of the neck of femur by open operation, and at 11.30 Dr. John Beattie will give an account of recent research at the Royal College of Surgeons. Any surgeons who would like to attend will be welcome at this meeting. The French surgeons will visit the Buckston Browne Farm at Downe, St. Bartholomew's and the London Hospitals, and attend a reception at the College on the same evening.

Mr. H. L. Eason has been re-elected vice-chancellor of the University of London for the coming session.

THE death last week of Mr. J. D. Unwin, Ph.D., puts an end to a career of singular promise. For twelve years Dr. Unwin had been collecting, digesting, and codifying facts relating to sex and culture, which were embodied in a book reviewed a few months ago in *THE LANCET* (1936, i., 437). He set out to test the hypothesis that what we call civilisation has been built up by compulsory sacrifices in the gratification of innate desires, and, although others might interpret differently the data which he analysed, the book placed Dr. Unwin as a pioneer in a new and very interesting branch of statistical sociology. He had been head for five years of Cambridge House where his vivid personality and clear thinking proved a stimulus to other social workers.

## PROGNOSIS

*A Series of Signed Articles contributed by invitation*

### CV.—PROGNOSIS IN ECLAMPSIA AND THE TOXÆMIA OF PREGNANCY

THE entity to which we apply the term toxæmia of pregnancy is at present but ill-defined. Its manifestations resemble those of chronic renal inefficiency. When this latter state of disordered function is complicated by pregnancy the conditions are liable to be confused. That chronic nephritis is very adversely affected by the course of pregnancy is well known, and it is also common knowledge that the prognosis in such cases is bad when the future health is considered. Indeed, Stander has computed that nearly 50 per cent. of women suffering from chronic nephritis and pregnancy are dead within five years of such pregnancy. It is not my intention to deal with this class of case, but to confine myself to a consideration of the prognosis in those cases in which signs of toxæmia have first appeared during the state of pregnancy.

Since the manifestation of toxæmia is so various, particularly as regards the severity of signs and symptoms, it is difficult to formulate any set scheme by which to arrive at a prognosis. It would seem advisable to consider first the state of eclampsia, and thereafter to endeavour to lay down some practical rules for our guidance in the less severe types of toxæmia.

#### ECLAMPSIA

Eclampsia may occur following or in the course of a mild toxæmia, but modern methods of treatment have reduced its incidence to about 1 per cent. in adequately supervised cases of albuminuria with concomitant toxic symptoms. About 5 to 10 per cent. of cases of eclampsia are fulminating in their onset and constitute a clinical drama of such intensity that the fate of the affected patient is a matter of only moments to her friends.

Brought face to face with a patient who has had an eclamptic fit, upon what evidence may we base an immediate prognosis? Certain facts will be forthcoming in the history, certain others will appear on a careful, general, and local examination, and yet a third mass of evidence will be accumulated by intelligent observation during the passage of the first few critical hours. Thus we may be able to build up a reasoned argument as to the chance of immediate recovery. From the *history* we may learn that the eclamptic condition developed suddenly without any complaint of previous ill-health. These fulminating cases always carry a grave prognosis. We may also learn the relationship between the attack and the labour. Of most serious prognostic import are those cases in which the eclampsia develops before labour begins. When labour has been completed the outlook is better, but not so good as it is when the condition arises during the actual process of parturition.

The *examination of the patient* will help prognosis in that certain signs which are of grave import are easily recognisable. A deep coma should always raise a doubt as to the patient's chance of immediate recovery, while the more normal her mental condition appears to be between her fits the more hopeful is the outcome. If her temperature is raised above 102° F. this in itself is a dangerous sign. I have never known a fatal case of eclampsia in which the temperature has been lower than 101° F. A con-

tinuously raised pulse-rate is significant in the same way. If the pulse continues at a rate over 120 between the fits the outlook is poor. Rapid respirations and other signs of pulmonary oedema constitute prognostic danger signals, while lack of general oedema is in my experience a most serious sign. Any degree of jaundice must be regarded as a very grave occurrence and should make us apprehensive of a fatal issue. Examination of the skin is, in my view, one of the most important ways of determining the severity of a case of eclampsia. If there is any skin action whatever the chance of recovery may be accounted good. The blood pressure is important, and it is generally recognised that a blood pressure of over 200 is a serious sign. Another investigation which may easily be made is to pass a catheter so as to gauge the amount of kidney activity. The passage of a catheter is deprecated by some on the grounds that it may precipitate another fit, but my own view is that the actual fits are not of grave importance and that the result obtained by catheterisation gives very valuable evidence. If a catheter specimen provides only about an ounce of blood-stained urine, of high specific gravity, and of a dark colour, loaded with albumin, the outlook is gloomy; whereas if a fair amount is obtained without any blood, the condition is proportionately less severe even though this specimen too is solid with albumin.

As the case proceeds we learn important facts which influence prognosis by carefully observing the *response to treatment*. First the recurrence of fits must be considered. I do not believe that frequently recurring convulsions are in themselves of serious prognostic import, but if the fits cease hope of recovery certainly becomes brighter, especially if at the same time there are signs of improvement in the general condition of the patient. The onset of *any* skin activity is a very hopeful incident; I have never observed the early signs of sweating in fatal cases. An improvement in the mental condition is also favourable, and if the patient becomes conscious within 12 hours I believe that the danger of a fatal result is very small. If no improvement is noted in any of these respects after six hours of treatment a very grave prognosis cannot be avoided.

During the course of treatment, at a time varying from 24 to 36 hours after the onset of the eclamptic state, a sudden very definite clinical improvement may be observed occurring within a very few hours. This is often synchronous with the intra-uterine death of the fetus, and within the next two days the delivery of a macerated child may be expected.

#### TOXÆMIC STATES AMOUNTING TO ECLAMPSIA

The more remote prognosis in these cases of eclampsia, as in the lesser toxæmias of pregnancy, is bound up with the amount of recovery which may take place in the efficiency of the kidney. When a patient has been under treatment for albuminuria of pregnancy with concomitant toxæmic symptoms and has recovered from her condition of ill-health it may safely be assumed that she will, if care is exercised for the rest of her pregnancy, proceed to term without developing any further disturbing symptoms. If recovery does not occur within a week or ten days it must be recognised that the chance of further improvement is small and that continuance of the pregnancy is fraught with danger of permanent

diminution in renal efficiency. If definite but not complete recovery takes place it is my conviction that many of these cases are hopeful and may be brought to a time suitable for an induction of premature labour without jeopardising the patient's future health. After delivery it will be found in cases of eclampsia that the amount of albumin in the urine will diminish very rapidly, and an early disappearance of this abnormal constituent should give rise to a confident hope that complete recovery will take place. The persistence of albumin in slight amount for more than eight weeks should raise a suspicion that the kidney has sustained some permanent damage. A rapid return of blood pressure to within normal limits also suggests a complete recovery from the initial toxæmia.

#### CONFUSIONAL STATES

A definite proportion of cases of eclampsia develop mental confusional states during the puerperium, and this fact should not be forgotten in framing a prognosis of the course and results of the disease. The incidence of mental derangement bears no relation to the severity of the original eclampsia. I have seen it supervene on clinically slight cases.

Eclamptic patients also show an increased morbidity in the puerperium and this fact must not be forgotten. It is, I think, accepted that an ultimate prognosis must be guarded in proportion to the length of the original illness, and if the patient has shown a toxæmia or eclamptic state which has been prolonged beyond three or four weeks it is very doubtful whether complete recovery ever occurs.

#### FUTURE PREGNANCIES

The possibility of danger on future pregnancies must always be carefully considered. The known fact that between 30 and 40 per cent. of patients exhibit recurring albuminuria in subsequent pregnancies must be borne in mind and an interval of at least eighteen months should be allowed to elapse before another pregnancy is undertaken. These subsequent pregnancies must always be watched most carefully from the earliest time, and the appearance of toxic symptoms within three months will immediately raise the question as to whether the pregnancy shall or shall not be allowed to continue.

Obstetrical Physician to Charing Cross Hospital.

## SPECIAL ARTICLES

### VITAMINS IN HUMAN NUTRITION VITAMIN-C RESERVES OF SUBJECTS OF THE VOLUNTARY HOSPITAL CLASS

BY LESLIE J. HARRIS, Sc.D., D.Sc.\*

M. A. ABBASY, M.B.

OF THE NUTRITIONAL LABORATORY, MEDICAL RESEARCH  
COUNCIL AND UNIVERSITY OF CAMBRIDGE; AND

JOHN YUDKIN, M.A., Ph.D.

OF ADDENBROOKE'S HOSPITAL, CAMBRIDGE

With a note by SIMON KELLY, M.B., B.Sc.,

M.R.C.P. Lond., D.P.H., D.P.M.

PHYSICIAN TO THE MANCHESTER VICTORIA MEMORIAL  
JEWISH HOSPITAL

SURVEYS have now been completed of the urinary excretion of vitamin C of a considerable group of subjects. As there may be some delay in the presentation in extenso of the rather numerous results it seems worth while to summarise the main conclusions reached.

The technique employed was the same as that previously described,<sup>1</sup> urine being collected in dark bottles in the presence of acetic acid and examined within 12 hours, the end-point in the titration being reached in less than two minutes.

*Control tests.*—In order to ensure the statistical significance of the results a further series of control tests has been carried out under rigorously standardised conditions. A group of 6 adult volunteers was first placed on a diet low in vitamin C, followed by a strict scurvy-producing diet—i.e., entirely devoid of all vitamin C—until their "reserves" had fallen to a markedly subnormal level, as indicated by the resulting low urinary output of the vitamin. The reputed "minimal-optimum" daily dose of ascorbic acid (25 mg.†) was then added to this vitamin-C-free

diet. The daily excretion thereupon gradually rose and finally, after about 42–49 days, became steady at 13 to 14.5 mg. (average 13.8 mg.) equivalent of reducing substance per day there being little variation between individual subjects. When this steady state had been reached, a good response on either the first or second day followed the administration of test doses of 700 mg.

This confirms, under more precise conditions, the approximate figures previously given. It appears therefore that if a subject excretes less than 13 mg. per day and fails to respond on the first or second day to a test dose of 700 mg. (per 10 st. body-weight), it is to be presumed that his diet has contained less than the reputed optimum of vitamin C.‡

In a further group of 11 adult subjects it was found that a daily supplement of 40 mg. of ascorbic acid (as orange juice) added to "normal" home diet not rich in fruit or vegetables (vitamin-C content estimated at only 15 mg. per day, making a total intake of 55 mg. per day) led to a daily excretion at equilibrium after 35 days of 25–29 mg. per day (av. 27 mg.). In a previous experiment the addition of a supplement of 90 mg. (estimated total = 105 mg.) led to the excretion of 49–56 mg. per day.

These results indicate that the daily output of vitamin C is governed by the past dietary intake of the subject and that (contrary to some supposition) there is little individual variation between different subjects or between subjects on different "basal" home diets. The detailed quantitative data for urinary responses for intakes lower than the reputed optimum, down to the definitely scurvy-producing "minimum," have still to be determined.

We have also obtained additional data illustrating a diminished excretion of vitamin C during pyrexia and toxæmia, indicating an apparently increased "loss" in the body in these conditions.

*Surveys on hospital patients.*—A group of 74 adult patients from both surgical and medical wards

\* Member of scientific staff, Medical Research Council.

† This optimum dose, 25 mg. of ascorbic acid, is equivalent to about 4.5 c.cm. of fresh orange juice—i.e., the greater part of the juice of a moderate-sized orange.

‡ As under ordinary circumstances the response to a test dose is proportional to the resting level, a measurement of the latter alone is sufficient for most routine tests of the kind here described.

were examined at Cambridge, nearly always within a few days after their admission to hospital. For the reason just mentioned, cases with marked pyrexia or toxæmia were excluded. The average excretion for the whole series was found to be as low as 8.9 mg. per day. Of the 74 subjects examined, no fewer than 62, representing 84 per cent. of the total, excreted less than the "minimum standard" (or "optimum") value of 13 mg. per day. Or, excluding a group of 19 subjects who had been on special diets for some time (see below), 43 cases (= 78 per cent. of the remaining 55 cases) excreted less than the "standard" of 13 mg. per day. The average excretion of the 55 cases was 10 mg. per day.

Results obtained with 30 children show a similar high proportion of cases with a "subnormal" excretion of the vitamin, which confirms preliminary conclusions on children reached previously in three other centres (at London and Birmingham) (control tests having shown that children receiving their adequate daily supplements of vitamin C gave "normal" excretions).<sup>1</sup>

From the appended note it will be seen that Dr. Kelly, who has carried out measurements by the same method at Manchester, has reached similar conclusions for a group of hospital patients in that city.

These results suggest that the intake of vitamin C of this class of the population is generally below the reputed optimum, as it is also below that of "normal" subjects (generally middle class) who have been examined in earlier tests in this country and in Holland, Germany, U.S.A., &c.<sup>2</sup> (daily excretion 20-35 mg.). This finding is in keeping with the conclusion of Orr,<sup>3</sup> based on a study of diet sheets, that about half the population receive less than their reputed optimum allowance of vitamin C.

*Inadequate diets in duodenal and gastric ulcer.*—A type of diet frequently prescribed in duodenal and gastric ulcer, containing little or no fruit juice, is deficient in vitamin C. It seems significant that among the lowest excretions of vitamin C observed in our series, a quite disproportionate number were of patients with gastric or duodenal ulcer. Thus included in our total of 74 adult subjects there were 12 cases of gastric or duodenal ulcer, and 7 cases of dyspepsia which had been on a "gastric diet." The 44 lowest excretions are found to embrace all of these 19 "gastric" cases (or the 29 lowest embrace 16 of them). The average daily excretion for the series of "gastric" cases was 5.6 mg. per day, the highest being 8.7 mg. (compared with an average of 10 mg. for the remaining 55 cases). Since in guinea-pigs deficiency of vitamin C may predispose to gastric ulcer,<sup>4</sup> the possibility of a vicious circle being set up in these conditions should be borne in mind. We would advocate the addition of the strained juice of one orange to the daily ration as a routine applicable for most "gastric" cases.

*Possible deficiency in certain hospital diets.*—In the course of this inquiry we have examined the various diet sheets of a number of representative hospitals. In several of these an adequate daily dose of orange juice has for some time past been included in the regimen as a routine. In others however it is still customary to give little or no fresh fruit (the patient is sometimes left to rely for fresh fruit on gifts brought in by his friends and relatives), and it is difficult to avoid the conclusion that there is a real danger of the diet containing less than the reputed optimum dose of vitamin C. We strongly urge that this question should receive careful attention from those in charge.

*Validity of the accepted figure for "optimum standard."*—It will be noticed that throughout we have been referring to the reputed optimum daily dose of vitamin C. The argument depends largely (at any rate in its more strictly quantitative deductions) on the actual validity of this generally accepted value. We hope to discuss this point in a later paper. In the meantime it may be remarked that the value for this "reputed minimal-optimum dose" is based on a variety of considerations, including (1) a knowledge of the amount of lemon juice needed to prevent the slightest symptoms of scurvy in mariners, and (2) the dose needed to restore subnormal capillary resistance caused by vitamin-C deficiency in human subjects to its normal strength. It will be understood that a small margin is allowed for the probable difference between the bare "minimum antiscorbutic dose" and the "minimal optimum dose"—a relation which in the case of guinea-pigs at least has been worked out with considerable accuracy.

Since so many individuals in certain sections of the population are found to be below the reputed optimum standard in their vitamin-C intake and yet may seem little the worse for it—superficially at any rate—critics may perhaps argue that the accepted standard is unnecessarily high. We think however that it would be a mistake to rush to this conclusion too hastily. A comparison may justly be made here with the accepted standard for the intake of iron and with the prevalence of "sub-clinical" nutritional anæmia. Laboratory tests have shown that a large proportion of subjects in poor-class districts may show some degree of nutritional anæmia compared with the accepted standards. Such individuals may exhibit no clear-cut symptoms of illness. Yet when extra iron is provided their general health and fitness improve, as evidenced for example by their diminished morbidity-rate.<sup>5</sup> A similar state of affairs may well be true for vitamin C, and indeed many suggestions have been made in the clinical literature in the past that a state of latent- or sub-scurvy is not uncommon. In any case, as the consumption of one orange per day is more than adequate to bring the intake up to the level of the reputed optimum—even supposing the diet to contain no other source of the vitamin—it would seem that the standard is sufficiently modest to make it a reasonable aim in practical dietetics.

Our thanks are due to the honorary staff of Addenbrooke's Hospital, in particular to Dr. G. S. Haynes and Dr. Leslie Cole, for their interest and generous help in this work. Messrs. Hoffmann-La Roche kindly provided us with the ascorbic acid used.

#### Note by DR. KELLY

A survey was made of the urinary excretion of vitamin C in 34 unselected adult patients admitted consecutively to the medical and surgical wards of the Manchester Victoria Memorial Jewish Hospital. The technique employed was that described by Abbasy, Harris, Ray, and Marrack<sup>1</sup> and the vitamin-C excretion was estimated almost each day from the day of admission. The following is a summary of the findings.

Of the 34 subjects examined 14 (41 per cent.) excreted less than the minimum standard of 13 mg. per day. The average excretion of the whole series was 16.7 mg. Four cases of diabetes, however, were included, whose diets were rich in vitamin C with correspondingly high figures (40 mg. or more). Excluding these cases the average excretion of the series was 13 mg. per day. In the series were 8

subjects aged 70 years or above, all of whom had low excretions on admission—an average of 10 mg. per day. The 8 cases of gastric or duodenal ulceration admitted for medical treatment excreted on admission above 13 mg. per day, but all showed a fall below that level after four days, reaching an average of 9 mg. after a week. The series also included 5 cases of pneumonia which on admission excreted above 13 mg. and all fell below that figure during the first week to an average of 6 mg. in spite of liberal drinks of orange juice.

The administration of two Redoxon tablets (100 mg. ascorbic acid) per day in all cases with low excretion figures raised the daily excretion to above 13 mg. in 3-7 days, irrespective of the clinical condition or state of illness. This had no discernible effect on the illness.

**Conclusions to Note.**—(1) Of 34 patients admitted to hospital, 14 showed evidence of vitamin-C subnormality, and most of the remainder excreted not more than the minimum standard. (2) All those above 70 years of age showed relative deficiency. (3) All those on dietetic treatment for gastric and duodenal ulceration showed deficiency after four days, though not on admission. The diet in use is deficient in vitamin C. (4) All the cases of pneumonia showed reduced excretion of vitamin C after a week, although receiving more than normally adequate amounts. (5) Correction of the vitamin-C deficiency had no obvious effect on the course of the illnesses. (6) Except for pyrexia and toxæmia, the only factor found influencing the amount of vitamin-C excretion was the amount of vitamin-C intake.

## INTERNATIONAL SOCIETY FOR MICROBIOLOGY

THE second international congress of this society will be held in London this year from July 25th to August 1st, Prof. J. C. G. Ledingham, F.R.S., presiding. The headquarters of the congress will be at University College, Gower-street, and all the scientific sections will hold their sittings there. Additional accommodation will be available in the adjacent London School of Hygiene and Tropical Medicine and the Wellcome Research Institute. The congress will be divided into eight sections:—

### General Biology of Micro-organisms

**Subjects discussed and Openers.**—Selective bacteriostasis: inhibitory action on the growth of bacteria and fungi of (1) substances of known constitution, and (2) products of the growth of micro-organisms; importance in the preparation of selective culture media (Prof. A. Fleming, London). Anaerobic bacterial metabolism (Dr. P. Fildes, F.R.S., London). Nutritional factors associated with the growth of micro-organisms (Dr. Lwoff, Paris). Variation: relation of changes in morphological and cultural characters to changes in chemical composition and to alterations in anti-

genic structure; toxin production and pathogenicity (Dr. J. A. Arkwright, F.R.S., London). Preservation of cultures of micro-organisms. Latency: methods of preservation of delicate organisms; preservation of virulence and antigenic structure; changes in the character of bacteria in culture media unfavourable for rapid growth (Dr. O. da Fonseca, Rio de Janeiro). Life-cycles of bacteria: symbiotic associations; filtrable forms (Dr. J. Ørskov, Copenhagen); bacterial photosynthesis (Dr. C. B. van Niel, Pacific Grove, California).

### Viruses and Virus Diseases in Animals and Plants

**Subjects discussed and Openers.**—The general characteristics of viruses, including bacteriophage (Prof. R. Doerr, Basel, and Dr. J. Henderson Smith, Rothamsted). Modes of transmission and paths of infection in virus diseases (Dr. E. Weston Hurst). Evidence concerning the agency of viruses in the aetiology of new growths (Dr. Peyton Rous, New York). Mechanism of immunity in virus diseases and practical applications thereof (Prof. J. C. G. Ledingham, F.R.S., London).

### Bacteria and Fungi in Relation to Disease in Man, Animals, and Plants

**Subjects discussed and Openers.**—The significance of serological and cultural types of bacteria and fungi pathogenic to man, animals, and plants in relation to epidemic, epizootic and epiphytotic outbreaks of disease (Prof. F. Neufeld, Berlin). Pathogenic streptococci: relation to scarlatina, puerperal fever, erysipelas, tonsillitis, acute rheumatism, and infective endocarditis in man, and to mastitis, lymphangitis, and suppurative conditions in animals (Dr. G. J. Hucker, Geneva, U.S.A.). Mycoses in man, animals, and plants; taxonomy; mechanism of pathogenic action; relation to saprophytic species and conditions of saprophytic growth (Mr. J. Ramsbottom, London). Bacteria causing acute inflammation of the alimentary tract and their mechanism of action (Dr. E. O. Jordan, Chicago). Pathogenic anaerobic bacteria (Prof. M. Weinberg, Paris).

### Economic Bacteriology, Soil, Dairying, and Industrial Microbiology

**Subjects discussed and Openers.**—The significance and estimation of the numbers and types of bacteria in milk, including thermophilic and thermophilic organisms; the need for adopting uniform methods (Dr. R. S. Breed, Geneva, U.S.A., and Dr. A. T. R. Mattick, Reading). Factors determining the behaviour of micro-organisms in milk and milk products (Mr. L. J. Meanwell, London). Yeast metabolism (Prof. A. Fernbach, Paris, and Prof. R. H. Hopkins, Birmingham).

The microbiology of water-supplies (Prof. F. E. Fritsch, F.R.S., London). The microbiology of perishable fresh foods, other than milk and milk products and the microbiology of canned foods, other than milk and milk products (Dr. L. H. Lampitt, London). The process of decomposition of plant remains in soil, manure, and compost heaps (Prof. E. Ruschmann, Landsberg a/Warthe). The microbiology of ensilage production (Prof. A. J. Virtanen, Helsingfors). The destruction and protection of woods and cellulosic materials (Dr. A. C. Thaysen, Teddington). Problems of biochemical purification of sewage and of trade effluents (Dr. H. Heukelekian, New Brunswick, U.S.A.). Recent advances in fermentation industries (Prof. T. Chrzaszcz and Dr. J. Janicki, Poznan).

The physiology of nitrogen-fixing organisms and the biochemistry of nitrogen fixation (Dr. C. Stapp, Berlin). The economic importance of the autotrophic and of certain anorganophilic bacteria (Dr. A. C. Thaysen).

### Medical, Veterinary and Agricultural Zoology and Parasitology

**Subjects discussed and Openers.**—The biology of the malarial parasites of man and animals (Lieut.-Colonel J. A. Sinton, I.M.S., Kasauli, India). Chemotherapy: mechanism of drug action and drug resistance (Dr. H. Schlossberger, Berlin). Factors which influence the transmission of infections by arthropod vectors (Prof. E. Brumpt, Paris). The parasitic nematodes of plants (Dr. P. Bovien, Copenhagen). Typhus fever and the rickettsias (Prof. H. Zinsser, Boston, U.S.A.). Immunity against animal parasites (Dr. E. Sergent, Algiers). Coccidia

in relation to domesticated animals (Dr. E. E. Tyzzer, Boston, U.S.A.).

### Serology and Immunochemistry

*Subjects discussed and Openers.*—The structure of natural and synthetic antigens (Dr. M. Heidelberger, New York). Immunity reactions in relation to antigenic structure and variation in bacteria (Prof. W. W. C. Topley, F.R.S., London). Principles and methods for the quantitative determination of antigens and antibodies, including their diagnostic application (Prof. Th. Madsen, Copenhagen). Blood groups and organ specificity (Prof. O. Thomsen, Copenhagen). The significance of allergy in disease (Dr. E. L. Opie, New York).

### Microbiological Chemistry

*Subjects discussed and Openers.*—Metabolic products of the lower fungi (Dr. P. W. Clutterbuck, London). Intermediate carbohydrate metabolism of micro-organisms (Prof. A. J. Kluyver, Delft). Influence of substrate on the chemical potentialities of the cell (Prof. H. von Euler, Stockholm).

### Specific Immunisation in the Control of Human and Animal Disease

*Subjects discussed and Openers.*—The control of diphtheria and whooping-cough by means of specific immunising reagents (Prof. W. H. Park, New York). The prophylaxis and serum treatment of human and animal diseases caused by anaerobic bacteria (Mr. T. Dalling, London). The serum treatment of pneumonia (Prof. J. G. M. Bullowa, New York). The relative value of antitoxic and antibacterial immunity in the prophylaxis and treatment of human and animal diseases in which the invasion by the causative bacterium may occur in a focal or generalised form (Dr. A. B. Wadsworth, New York). The relative value of antitoxic and antibacterial immunity in the prophylaxis and treatment of human and animal diseases, &c.—second day (Dr. F. Gerlach, Mödling bei Wien).

### GENERAL PROGRAMME

Mr. Ramsay MacDonald, Lord President of the Council, will declare the congress officially open at a reception to be held in the great hall of University College, at 9 P.M. on Saturday, July 25th. A reception for the delegates will be given by H.M. Government at Lancaster House, St. James's, at 10 P.M. on July 27th when Sir Kingsley Wood, Minister of Health, will act as host. On July 28th, at 8.30 P.M., the delegates will be the guests of the Royal Society of Medicine at the society's house, 1, Wimpole-street, W., and on July 29th the Royal Society is holding a reception at Burlington House, Piccadilly, W., at 8.30 P.M. The official banquet of the congress will take place at the Trocadero Restaurant, W., at 8 P.M., on July 31st.

From July 27th to 29th an exhibition of scientific instruments—open to non-members of the congress—will be held in the physics department of University College. Microscopes, microprojectors, centrifuges, vacuum pumps, stains, and reagents will be displayed in great variety, and many of the exhibits will be shown for the first time. A number of cinematograph demonstrations will be given at the London School of Hygiene and Tropical Medicine, Keppel-street, W.C., on July 30th at 5 P.M. and on July 31st at 2.30 P.M. Other demonstrations to be given by members of the congress will include the following:—

Significance of allergy in disease (Louis Dienes, Boston, U.S.A.). Growth of coloured bacteria on paper (Prof. A. Fleming, London). Procedure and apparatus for preservation in "Lyophile" form of serum (Drs. E. W. Florsdorf and Stuart Mudd, Philadelphia, U.S.A.). Methods of estimating the effect of chemotherapeutic substances on pathogenic organisms (Prof. von Janesco, Szeged, Hungary). A new group of microbes occurring as symbionts of bacteria and independently (E. Klieneberger, London). Isolation and dissection with the Schouten micro-manipulator (S. L. Schouten, Utrecht,

Holland). A mechanical device which prepares and inoculates rolled tubes (Dr. Redvers Thompson, Ontario, Canada).

Visits will be made to places of scientific and general interest in and near London and also to Oxford and Cambridge. The executive committee invites all who are interested in microbiology to send for a registration form and further particulars from Prof. J. C. Drummond, University College, Gower-street, London, W.C.1.

## EDINBURGH MEETING OF THE BRITISH HOSPITALS ASSOCIATION

(FROM OUR SCOTTISH CORRESPONDENT)

### WAITING-LISTS

At the annual conference of the British Hospitals Association, which opened in Edinburgh on June 18th, Mr. John Fraser, professor of clinical surgery in the University of Edinburgh, read a paper on hospitals and waiting-lists. He said that in some measure the waiting-list could be regarded as a compliment to the institution with which it was associated, and in a teaching hospital it was essential, for it provided a source for the supply of teaching material. On the other hand, the arguments against waiting-lists were open to no question; they were contrary to humanitarian principles, for he questioned whether at any time delay was beneficial, though it might be inevitable. Further, waiting-lists were economically unsound. He had found that on the waiting-lists of 21 of the larger of the general hospitals of England and Scotland there were nearly 20,000 names. Of these probably fully 56 per cent. would be restored to full working powers within a reasonable time after treatment. The loss in terms of work was thus great. The waiting-lists chiefly comprised the cases known as chronic, and in this class they found such conditions as hernia, hydrocele, hæmorrhoids, and injuries and chronic infections of joints. If looked at from the economic standpoint these were the very conditions which should have early attention, but pity and humanity had fixed the standards by which they judged urgency, and the consensus of opinion supported the plea, though no doubt the economist would contest the issue. In certain areas during the past decade the waiting-list figures had risen by 71.4 per cent., while the bed increase had only been 16.9 per cent. Among the reasons for the increase he mentioned the greater tendency to seek hospital treatment, the influence of the Insurance Act, and the larger number of emergency admissions. Motor transport had facilitated the transference of acute cases to hospital, though it was also responsible for some of the most serious emergencies.

Turning to the question of finding a remedy, Prof. Fraser referred to the development of local authority hospitals, but pointed out that these lay under the disadvantage that payment was required, and that this fact, combined to some extent with the influence of precedent, status, and tradition, had so affected the position that the burden of the waiting-lists in voluntary hospitals had in no way been lightened. What then was to be done? He had been impressed by the record of one hospital in particular where there was no waiting-list. This was achieved, first, by limiting emergency admissions to a definite ration, the remainder being sent to municipal and other institutions. Secondly, a proportion of the contributions from workers' organisations had been used to defray the costs of a ward for the less urgent type of surgical cases. He was satisfied that

the adoption of these principles would go a long way towards solving a serious problem.

At the afternoon session Aldermen W. Hyde read a paper on the future policy of contributory schemes and their relation to voluntary hospitals. He drew attention to the consistent expansion of the hospitals contributory schemes since the late war. Under the British Hospitals Contributory Schemes Association more than 100 schemes were affiliated, representing an annual collection exceeding £2,400,000, and it was estimated that the total amount raised by contributory schemes of all types exceeded £3,000,000. He suggested the formation of a consultative joint committee for the purpose of unifying the policy of the various schemes.

#### TREATMENT OF FRACTURES

At the meeting on the following day Mr. R. C. Elmslie, in an address on the treatment of fractures, made a strong plea for the development of fully equipped fracture units throughout the country. In the treatment of fractures, he said, only the very best would do. Referring to the huge number of industrial and road accidents occurring daily, he pointed out that most of these injuries when severe involved fractures, many of which were complicated and required expert treatment if a good result was to be obtained. The lessons taught by war experiences were the saving of life by first aid, the advantages of segregation and team-work, the necessity for physical and gymnastic treatment and for occupational therapy, and the use of convalescent camps and command depôts. He said that some of the worst results of treatment of fractures were those he found in the cottage hospitals and in the smaller provincial towns. The staffs of these hospitals were often general practitioners, and it was a matter of chance if there was some one with the mechanical ability essential for the treatment of fractures. He said that hospitals that had not established fracture units ought to give up the treatment of fractures. In his opinion, they should act as first-aid stations and should transfer the cases of fractures to properly equipped centres.

### BRITISH ASSOCIATION OF RADIOLOGISTS

THE second annual general meeting of the British Association of Radiologists was held at the Royal Infirmary, Manchester, on June 12th and 13th; the 75 members present included radiologists from all over the country.

On June 12th, after the business meeting, Dr. R. S. PATERSON, of Manchester, delivered his presidential address. He spoke of the zeal and initiative of Dr. J. F. Brailsford, who was responsible for founding the association, and then summarised its progress during the past year, outlining also the activities it was hoped to undertake in the future. He emphasised the importance to radiology, from the clinical, ethical, and educational points of view, of an association with a membership limited to medical men practising radiology exclusively. As an instance of the educational advantages, he drew attention to the foundation by the association of a fellowship which would constitute a higher diploma in the speciality.—Dr. F. Hernaman-Johnson, warden of the fellowship, then gave an address on its aims and objects.

The morning of June 13th was devoted to clinical

papers. The president had arranged a symposium on the Radical X Ray Treatment of Malignant Disease in which after he had set out general principles the following took part: Dr. J. Struthers Fulton (Glasgow) spoke on Skin Tolerance; Dr. J. H. Douglas Webster (London) on Malignancy in the Larynx and Pharynx; Dr. Ffrangcon Roberts (Cambridge) on Malignancy in the Oesophagus; Dr. J. E. A. Lynham (London) on Malignancy in the Breast; and Dr. J. F. Bromley (Birmingham) on Malignancy in the Skin. Subsequently, four diagnostic papers were read: Fractures of the Facial Bones by Dr. H. K. Graham Hodgson (London); Complications of Gastro-enterostomy by Dr. S. Cochrane Shanks (London); Cæcal Filling Defects by Dr. J. Burnett King (Edinburgh); and Observed Changes in the Intervertebral Discs following Lumbar Puncture by Dr. J. L. A. Grout (Sheffield).

During the meeting an exhibition of radiograms was on view. A visit was paid to the research department of Messrs. Armstrong Vickers, where the apparatus demonstrated included a new million-volt generator and X ray deep therapy tube. Dr. Russell J. Reynolds gave a demonstration of his latest apparatus for cineradiography.

The annual dinner of the association was held at the Midland Hotel on June 12th, with the president in the chair. Among the official guests were Prof. J. Morley, Prof. E. D. Telford, Prof. F. E. Tylecote, Prof. A. Ramsbottom, Prof. D. Dougal, Mr. G. J. Jefferson, Mr. H. Platt, and Mr. W. Cobbett, chairman of the board of management of the Manchester Royal Infirmary, who responded to the toast of the guests proposed by Dr. Shanks. The toast of the association was proposed by Mr. Jefferson, Dr. E. W. Twining and Dr. Hernaman-Johnson responding.

### MEDICINE AND THE LAW

#### Prosthetic Dentists

PROTHESIS has for centuries connoted to grammarians the addition of a letter or syllable at the beginning of a word. In the literature of surgery the word has been applied to the addition which fills up some deficiency and especially to the making of artificial arms and legs where the natural limbs are lost. From prosthetic surgery it is a short step to prosthetic dentistry; but here this noble-sounding Greek epithet has been adopted by the Society of Prosthetic Dentists of which the Lord Chief Justice had a good deal to say last week in the libel action of Canon and MacDonald v. the British Dental Association. The plaintiffs complained of a passage, headed "National Denture Clinic," which was part of a lengthy report of the proceedings of the representative board of the defendant body at a meeting held in April, 1935. The passage nowhere mentioned either Mr. Canon or Mr. MacDonald: it referred to a clinic set up in Hugh-street, Pimlico, which "professed to be an institution solely for the supply of dentures to the deserving poor." It spoke of a wide appeal for funds made in the press and of house-to-house collections. "While the ostensible object of the clinic may be entirely praiseworthy, there were certain features of the organisation which the Council thought required very close scrutiny." The plaintiffs built up their allegation of libel mainly upon the twin foundations of those phrases "professed to be" and "required very close scrutiny." Plaintiffs who complain of defamation must say exactly what they complain of. Mr. Canon and Mr. MacDonald said

that the defendant association's words meant that the plaintiffs conducted the clinic in a dishonest manner, that the public was deceived by spurious appeals for funds, and that the funds were misapplied by dishonesty or incompetence.

At the conclusion of the evidence and the speeches of counsel the Lord Chief Justice gave the special jury a vigorous summing-up. What, he asked, was there derogatory in saying that an organisation "professed to be" an institution solely for the supply of dentures for the deserving poor? What was there derogatory in saying that it must receive close scrutiny? All human activities of a public nature required and received the closest scrutiny; it was good for the public and for the officials. Lord Hewart passed on to discuss the origin of the Dentists Act, 1921. There had previously been neglect of dentistry and of the rights of the public in relation to dentistry. "To-day you may hear the praises of the great and invaluable profession of dentistry on all men's lips as the result is in most men's mouths." The Act was passed in the interests of the public, of whom poor people formed a large part. Rich people could look after themselves; people of moderate means, or of no means at all, required protection; they were open to be imposed upon by incompetent persons, by quacks who were not qualified. "It is necessary that persons who practise a skilled profession shall have the requisite degree of skill, shall subject themselves to certain tests, and shall be qualified—so it is with barristers, solicitors, accountants, doctors, surgeons, and almost every branch of skilled calling where men practise an art in relation to the health, lives, or fortunes of their fellow-men." Section 14 (2) of the 1921 Act defined the practice of dentistry as including the performance of any such operation and the giving of any such treatment, advice, or attendance as is usually performed or given by dentists; anyone who performs an operation or gives treatment, advice, or attendance "preparatory to or for the purpose of or in connexion with the fitting, insertion, or fixing of artificial teeth" is deemed by Section 14 (2) to have practised dentistry within the meaning of the Act. Dental mechanics might think they could do the work just as well as the registered dentist, but the law said they must not try. The case showed, said Lord Hewart, that there was a body of persons calling themselves "prosthetic dentists" who were dental mechanics wishing to be regarded as, and to act as, dentists. The word "prosthetic" merely meant that something was added. Prosthetic dentists added teeth to the jaw and might as well call themselves dental dentists. If the Society of Prosthetic Dentists had its way, it would get rid of Section 14 of the Act so that an unqualified person might fit a mouth with artificial teeth—"that would be good for the prosthetic dentists but it would not be good for the body politic." The Lord Chief Justice suggested that the British Dental Association, a body charged with the duty of watching the professional skill of dentists and seeing that those who practised as dentists conformed to the statutory provisions, was thoroughly justified in keeping an eye on the prosthetic dentists. It was unfair to represent the Association's efforts as the efforts of a professional body to keep out outsiders and to prevent competition; "only the most ignorant or thoughtless persons would regard them in that way." Some people, said Lord Hewart, might regard the Bar as a close corporation which aimed at preventing outsiders from doing legal work; but it was in the interests of the State and of the public that where professional work was to be done, there should be

high professional training. There had been a virtual admission by Mr. Canon that the plaintiffs' real object was commercial—that was to say, that the Society of Prosthetic Dentists might become a powerful trade-union from which the plaintiffs might draw a salary. Lord Hewart invited the jury to conclude that these persons (who were strongly of opinion that the dental mechanic, the artisan of the business, should be freed from the trammels of the law) formed a society under this curious name and, to get prestige for the society, associated with it this clinic mainly supported by the contributions of well-disposed persons. The National Denture Clinic had three dentists to 17 or 18 mechanics. Undoubtedly its staff attended to the dental needs of the poor, but had it not been made clear that there were clever people in the background whose intention it was to use the prestige of the clinic to assist a movement to enable the mechanic to act as a dentist? Was not this an organisation which called for special scrutiny from the British Dental Association? At the close of the summing-up the jury made short work of the plaintiffs' claim. It found that the words complained of were not defamatory and it added a rider that, while many poor and destitute persons had received benefit from the plaintiffs' organisation, the jurors were not persuaded that the organisation was entirely a charitable institution. Judgment was thereupon given for the defendants with costs and the sensitiveness of the plaintiffs is found to have been excessive.

It is tempting to apply Lord Hewart's remarks about dentistry to the practice of medicine and surgery. He certainly insisted that the public has an interest in the recognition of standards of professional skill in all skilled professions. He certainly rebukes those who would suggest that statutory restrictions are enforced for the benefit of professional monopoly. The 1921 Act gave the dentists a protection from unqualified competitors which is vastly more vigorous than the slender restrictions on the unqualified doctor or the quack surgeon. Perhaps one must not press the recent case too far. To go back to the grammarians with whom these notes began, a scholar who wrote on "Grimm's Law" some fifty years ago observed that Prosthesis in the grammatical sense "belonged to a class of terms denoting arbitrary processes whose intrusion into the realm of language should be viewed with suspicion." The result of Canon and MacDonald *v.* the British Dental Association is to show that the intrusion of prosthetic dentists into the realm of dental practice is to be viewed similarly.

#### Traffic Accident Due to Fainting Fit

The compulsory insurance of motorists against third-party risks is often disappointing to the injured pedestrian or bicyclist. Parliament has not provided that the motorist shall always pay; it has merely provided that, if the motorist must pay, there shall be no default in the payment. The motorist is liable for his negligent driving but not for the consequences of sheer accident. At Southend county court a motorist was lately sued by a boy of 15. The car had suddenly swerved, had crashed through a row of bicycles placed on the kerb, and had pinned the boy against a gate. The boy was badly hurt. Two doctors, called for the defence, supported the view that the motorist had a fainting fit which caused the accident. The plaintiff's case was that the accident caused the fainting fit. There was medical evidence that the motorist had never fainted before and was physically a fit man. The judge held that the

fainting fit caused the accident; the motorist's defence that the accident was inevitable and was nobody's fault was thus established.

If the recovery of damages under the compulsory insurance enactments is thus seen to depend upon the motorist's negligence, the right to recover damages is not limited to recovery through the insurance companies where negligence is proved. There has lately been a High Court case where a motorist recovered from his insurance company the sum of £600 as compensation for injuries received through

another motorist's negligence. It then occurred to him to pursue his common-law right to obtain damages against the man whose negligence had caused him the injuries. The insurance companies behind the respective motorists endeavoured to dissuade the would-be plaintiff from bringing his action. The companies have a "knock-and-knock" system with which they are mutually content. The injured motorist, however, proceeded with his claim and the court held that there was no legal reason why he should not get his damages twice over.

## THE SERVICES

### INDIAN MEDICAL SERVICE: ANNUAL DINNER

MORE than one hundred officers of the Indian Medical Service dined together on June 17th at the Trocadero, when Major-General Sir Robert McCarrison, C.I.E., presided. The members of the Service present were as follows:—

*Major-Generals:* Sir Frank Connor, D.S.O., K.H.S.; W. V. Coppinger, C.I.E., D.S.O.; Sir James Graham, C.B., C.I.E.; Sir John Megaw, K.C.I.E.; H. R. Nutt, K.H.S.; T. G. F. Paterson, D.S.O., K.H.P.; and G. E. Tate, C.I.E.

*Colonels:* H. Ainsworth; J. Anderson, C.I.E.; Sir Charles Brierley, C.I.E.; Sir Samuel Christophers, C.I.E., O.B.E.; H. M. Cruddas, C.M.G., O.B.E.; A. B. Fry, C.B., C.I.E., D.S.O.; J. Fuller-Good; C. A. Gill; T. A. Granger, C.M.G.; C. R. M. Green; E. C. Hodgson, D.S.O., K.H.P.; W. H. Leonard, C.B.; H. M. Mackenzie, C.I.E.; Sir Richard Needham, C.I.E., D.S.O.; A. H. Proctor, D.S.O.; A. J. H. Russell, C.B.E., K.H.S.; Ashton Street; and R. G. Turner, C.M.G., D.S.O.

*Lieut.-Colonels:* C. H. P. Allen; W. G. P. Alpin, O.B.E.; A. C. Anderson; S. Anderson; C. H. Barber, D.S.O.; J. W. Barnett; A. N. Bose, M.B.E.; R. H. Bott, C.I.E.; H. Chand, M.C.; H. P. Cook; A. G. Coullie; D. G. Crawford; J. M. Crawford, O.B.E.; H. J. M. Cursetjee, D.S.O.; J. B. Dalzell Hunter, O.B.E.; H. R. Dutton, C.I.E.; S. C. Evans; J. K. S. Fleming, C.B.E.; T. H. Gloster; C. A. Godson, M.C.; G. F. Graham; V. B. Green-Armytage; A. E. Grisewood; A. F. Hamilton, C.I.E.; W. G. Hamilton; W. L. Harnet, C.I.E.; J. M. R. Hennessy; H. Hingston; J. M. Holmes; E. V. Hugo, C.M.G.; M. L. C. Irvine; I. Davenport Jones; W. D. Keyworth; H. H. King, C.I.E.; E. W. O'G. Kirwan; E. C. G. Maddock, C.I.E.; W. A. Mearns; P. S. Mills; H. E. Murray; F. O'Kinealy, C.I.E., C.V.O.; A. N. Palit; H. Ross, C.I.E., O.B.E.; H. K. Rowntree, M.C.; J. D. Sandes, R. B. S. Sewell, C.I.E.; W. S. J. Shaw; A. L. Sheppard; J. A. Sinton, V.C., O.B.E.; T. G. N. Stokes; H. Stott, O.B.E.; W. A. Sykes, D.S.O.; C. Thomson; F. R. Thornton, M.C.; E. Owen Thurston; A. G. Tresidder, C.I.E.; E. L. Ward, C.B.E.; E. E. Waters; and W. J. Webster, M.C.

*Majors:* R. S. Aspinall, C.I.E.; H. C. Brown, C.I.E.; J. A. Cruickshank, M.C.; A. J. Culhane; Sir T. Carey Evans, M.C.; G. R. McRobert; C. G. Seymour; and R. A. Wesson.

*Captains:* J. H. Boulton; W. Happer; G. Milne; W. J. L. Neal; M. H. Shah; and Jaswant Singh.

*Officers on probation:* Lieut. K. I. E. Macleod; Lieut. G. R. C. Palmer; Lieut. J. G. Thomson; Lieut. A. C. Taylor; Lieut. T. Sommerville; and Lieut. L. S. F. Woodhead.

The last six mentioned were present by invitation and the other guests were Mr. F. H. Brown, C.I.E. (*The Times*), Dr. N. G. Horner (*British Medical Journal*), Dr. Egbert Morland (*The Lancet*), and Mr. J. S. Simpson (India Office).

Sir ROBERT McCARRISON in proposing the toast of an "Ancient and much loved Service" read telegrams of congratulation from the director-general in India and the inspector-general of the Punjab. "Ichabod," he said, was not true of the I.M.S., the glory was not departed; in view of the funda-

mental reforms in progress there was no time when it was so necessary for the Service to give of its best. And he lightly but firmly sketched the many ways in which the I.M.S. had advanced the prosperity of India and was still prepared to lead India "along the right, and now the appointed, way."—Sir JOHN MEGAW proposed "The Chairman," with admiration based on personal knowledge of forty years, and coupled with the toast the name of Lady McCarrison whose moral and intellectual help had supported her husband in directing the nutrition research laboratories at Coonoor and in advancing there the study of vitamin deficiency.—Sir Robert responded with a simple "I thank you," and asked his fellow officers to applaud the team-work of the hon. secretaries Sir Richard Needham and Sir T. Carey Evans. After which Colonel Anderson told some stories.

### INDIAN MEDICAL SERVICE

Bt. Cols. to be Cols.: A. J. H. Russell, C.B.E., K.H.S., and H. H. Thorburn, C.I.E. Lt.-Col. J. Taylor, D.S.O., V.H.S., to be Col.

Capt. (now Maj.) F. M. Collins, I.M.S.; relinquishes the local rank of Maj. on ceasing to hold the appt. of Surg. to H.E. the Viceroy.

Majors J. C. Coutts, R. A. Bennett, and R. A. Anderson, of the R.A.M.C., have been posted to Rawalpindi, Lahore, and Meerut Districts respectively, as specialist in radiology, specialist in medicine, and D.A.D. of Hygiene.

Major A. L. Robb, R.A.M.C., vacates his appointment as M.O. at Army Headquarters, Simla, on July 20th.

### ROYAL NAVAL MEDICAL SERVICE

Surg. Comdrs. L. F. Strugnell to *Pembroke* for R.N.B.; and J. C. Kelly, D.S.C., to *Amphion*.

Surg. Lt.-Comdr. C. T. Hyatt to *Drake* for R.N.B.

Surg. Lt. D. Ewart to *Royal Oak*.

Mr. A. H. D. O. Richmond has been appointed Admiralty Surgeon and Agent for Grimsby, and Mr. H. Douglas Ord Surgeon and Agent for South Shields.

### ROYAL NAVAL VOLUNTEER RESERVE

Surg. Lt.-Comdrs. J. L. Cox to *Curacoa*; E. G. Thomas to *Iron Duke*; H. G. Ungley to *Excellent*; and C. C. Ungley to *Pembroke*.

Surg. Lts. S. B. Levy to R.N. Hosp., Haslar; and J. F. Corr to *Curacoa*.

Proby. Surg. Lts. P. S. Luffman to *St. Vincent*; and T. D. G. Wilson to *Iron Duke*.

Surg. Sub-Lt. D. S. Macphail to *Victory* for R.N. Hosp., Haslar.

### ROYAL ARMY MEDICAL CORPS

Capt. W. H. Hargreaves is placed on the h.p. list on account of ill-health.

Short Service Commissions: Lt. (on prob.) J. A. Farfor resigns his commission; J. A. G. M. Lynch to be Lt. (on prob.).

### REGULAR ARMY RESERVE OF OFFICERS

Maj. A. G. Cummins, M.C., having attained the age limit of liability to recall, ceases to belong to the Res. of Off.

### TERRITORIAL ARMY

Capt. and Bt. Maj. J. Carver and Capt. T. S. Torrance to be Majs.

Lts. K. G. W. Saunders and G. O. Gauld to be Capts.  
Capt. J. E. Snow to be Divl. Adj. 49th (W. Riding)  
Div.

The Efficiency Decoration has been conferred upon  
Lt.-Col. H. V. Walsh.

#### ROYAL AIR FORCE

Squadron Leader F. B. C. L. B. Crawford to Home  
Aircraft Depôt, Henlow.

Flight Lt. C. Crowley to R.A.F. Depôt, Uxbridge.

E. W. R. Fairley and R. C. O'Grady are granted short  
service commissions as Flying Offrs.

Flying Offr. E. H. E. Cross to R.A.F. Station, Upper  
Heyford, on appointment to a short service commission.

*Dental Branch.*—Flying Offrs. A. P. Britton to No. 1  
School of Technical Training (Apprentices), Halton;  
and A. J. S. Wilson to Home Aircraft Depôt, Henlow.

#### DEATHS IN THE SERVICES

Lt.-Col. BELL WILMOTT LONGHURST, R.A.M.C. ret'd.,  
who died on June 15th in his 70th year, was the eldest  
son of the late Sir (Henry) Bell Longhurst, surgeon dentist  
to King Edward VII. Educated at King's College,  
London, he qualified M.R.C.S. in 1891 and after holding a  
house appointment at King's College Hospital joined  
the R.A.M.C., becoming Lt.-col. in 1915. He was in South  
Africa from 1899-1902. In the European war he was in  
charge of the Lahore British General Hospital, France,  
and in 1919-1920 of the 21st General Hospital at  
Alexandria. In 1921 he took the D.T.M. Liverp. and  
specialised in tropical medicine. He found recreation  
in rowing and swimming, being the winner of various  
prizes. He married Eleanor, daughter of Mr. W. O.  
Jarratt, and after his retirement went to live at Bath.

## PANEL AND CONTRACT PRACTICE

### Irregular Certification: A Contrast

AN insurance committee in the south has just  
dealt with three cases in which insurance practi-  
tioners have issued certificates irregularly; in one  
case the doctor was censured—possibly because four  
attempts had been made to secure his services with-  
out success, and he did not attend before the medical  
service subcommittee, contenting himself with writing  
a letter a few hours only before the meeting—and  
in the others the practitioners were merely warned  
that they must comply with the Medical Certification  
Rules. The circumstances in one of these cases are  
worthy of examination; the insured person had  
been on the funds of the society since 1932 with  
heart trouble. In May, 1933, she went to hospital  
until the following December, and then was under treat-  
ment by Dr. A throughout 1934 and until March 7th,  
1935, and fortnightly thence until May 1st, 1935.  
Dr. A did not see her again until March 23rd, 1936,  
but continued to provide prescriptions and certifi-  
cates, which were collected by a child. The practi-  
tioner's evidence was that every time he went to  
see the insured person she collapsed owing to her  
heart condition; that she was very nervous and  
excitable; that he used to pull up his car further  
down the road so that the insured person would not  
know that he was coming to see her; that every  
time he left her in a state of collapse; that he  
explained to the patient's mother why he would not  
call too frequently; that he knew exactly how the  
patient was getting on; that he told the mother  
that if any change in her condition made it necessary  
for him to see her he would come at once if sent  
for; that the insured person lives only 100 yards  
from his surgery; that he admitted issuing the  
certificates without actually seeing the insured person.  
At the meeting of the subcommittee it was sug-  
gested to Dr. A that it would have been better to  
have written to the society stating that he thought  
it inadvisable to visit the patient—for societies are  
empowered in suitable cases to waive the necessity  
for regular medical certificates. The subcommittee  
found that the doctor had committed a breach of  
the rules but they were of opinion that in not visiting  
the insured person the practitioner acted in the best  
interests of the patient, and recommended that he  
should be informed that he must in future comply  
strictly with the Medical Certification Rules. It is  
noteworthy that the period during which the patient  
was not seen by her doctor extended from May, 1935,  
to March, 1936.

As a contrast a neighbouring committee some  
time ago dealt with a similar case—of cardiac trouble

and cataleptic fits and a lengthy period during  
which certificates were issued without examination.  
The doctor told the subcommittee that the patient  
was suffering from major hysteria and mental trouble,  
and that the excitement caused by his visits did her  
more harm than good. The subcommittee quoted No. 9  
of the Certification Rules, and found it "abundantly  
clear" that the doctor, in contravention of that  
rule, issued certificates on dates when he did not  
see the patient. The practitioner must have known  
that he appended his signature to statements which  
were not true, and he seemed to have failed properly  
to appreciate that the form of certificate supplied  
for the use of practitioners contains a statement  
of fact. The committee pointed out that it was  
open to the practitioner to have informed the approved  
society that the condition of the patient had reached  
the stage where no further medical treatment was  
possible for the patient's disability, and of his view  
that his visits, by exciting her, would do more harm  
than good. The society would then have been in a  
position to make other inquiries if they thought fit.  
A fine of £5 was recommended with the rider that  
had he not explained his omission to visit the patient  
as dictated by medical considerations they would  
have suggested a larger amount. The fact that  
the £5 was actually withheld may be taken as  
indicating the Minister's view of the matter.

### Intravenous Injections

The Kent insurance committee have recently  
concurred in the decision of the local medical and  
panel committee that intravenous injections of neo-  
salvarsan are not beyond the range of service of a  
general practitioner. In the case under review,  
however, the service did not fall within the scope of  
the practitioner's obligations under the terms of  
service as it was given in a general hospital with a  
limited staff. The Minister has indicated that he  
does not propose to refer the case to referees.

### "No Smoking"

Mr. X, an insured person, complained to the  
Birmingham insurance committee that Dr. A,  
assistant to Dr. B, had failed to provide him with  
treatment. The story as told to the medical service  
subcommittee was as follows:—

Mr. X said he suffered from bronchitis and on  
March 27th last he developed an affection of the throat.  
Having passed a very bad night he attended next morning  
at the surgery where, although a notice that smoking  
was strictly prohibited was exhibited in the waiting-room,  
Dr. A's clerk was smoking a cigarette. As the smoke  
affected his chest Mr. X asked the clerk to be kind enough

to stop smoking. After waiting some time he was summoned to the consulting-room where Dr. A also was smoking. He asked the doctor if he would be kind enough to put the cigarette on one side, to which he replied with a paraphrase of "An Englishman's home is his castle" and continued smoking. Mr. X then told Dr. A that his throat and chest were very bad and asked for a prescription for medicine similar to that prescribed by Dr. B and also a strong gargle for the throat. He explained that what he wanted was a yellow medicine and alleged that Dr. A referred to a book, wrote out a prescription, tore it up, and refused to give him treatment. Mr. X lost his temper and left the consulting-room without treatment. Next day he saw Dr. B who prescribed medicine and gargle, and after a few days in bed the condition of the throat improved.

In his own account Dr. A said that Mr. X entered the consulting-room and in an abusive manner complained that the clerk and he were smoking. He asked Mr. X to be civil but he became more abusive and demanded a prescription for medicine and gargle. As he had not seen Mr. X before when suffering from a bad throat he told him he wished to examine his throat, adding that he would not smoke during the examination. Mr. X refused to submit to examination and Dr. A thereupon declined to issue a prescription and advised him to see Dr. B if he did not wish to be examined by Dr. A. Dr. A denied having torn up the prescription; he had not even written it. He added that he remained quiet while the insured person was abusing him and that Mr. X had previously attended for treatment while he was smoking without raising any objection.

Mr. X denied using certain bad language attributed to him and stated that the doctor did not ask to examine his throat, and consequently he did not refuse to be examined.

The subcommittee pointed out that the evidence was contradictory. They were, however, satisfied that Mr. X and Dr. A irritated each other, that they became excited and consequently neither of them was able to give a concise statement of what actually had taken place. They were satisfied that Mr. X applied for treatment on March 27th, that he was in need of treatment and that treatment was not provided, and that in failing to provide treatment Dr. A had not complied with the terms of service. As, however, the evidence as to the cause of failure was so conflicting, they recommended the insurance committee to take no action.

(FROM OUR OWN CORRESPONDENT)

### PAYMENT FOR ANTI-DIPHTHERIA IMMUNISATION

It is unfortunate that a difference of opinion should have arisen between the medical profession of the Irish Free State and the Department of Local Government and Public Health on the question of the remuneration to be paid to medical men for carrying out schemes of immunisation against diphtheria under the direction of the county medical officers of health. The profession is willing to cooperate in what it believes to be a beneficent measure of public health, but it demands that its services should be adequately remunerated. No difference arose between the professional organisations and the local authorities on the question of payment, but the Department refused its sanction to the fees the local authorities were willing to pay. The sums at issue are small, and it is unfortunate if a service beneficial to the health of the community is hindered or hampered by so small a matter. In some quarters blame is put on the profession for not accepting the fees approved by the Department, and it is being

suggested that it is the duty of medical men to serve the public good regardless of remuneration. Nothing is more likely to prevent a friendly arrangement than imprudent demands of this kind. The responsibility for carrying out the immunisation schemes rests on the Department of Local Government and Public Health and on the local authorities. The latter make no complaint of the fees asked for by medical practitioners, and the block comes from the Department.

## THE BIRTHDAY HONOURS

THE list of honours conferred by the King on his 42nd birthday contains the following names of members of the medical profession:—

### Viscount

Lord Dawson of Penn, P.C., G.C.V.O., K.C.B.,  
K.C.M.G., M.D., P.R.C.P.  
Physician in Ordinary to H.M. The King.

### G.C.V.O.

Sir Richard Robert Cruise, K.C.V.O., F.R.C.S.  
Surgeon oculist to H.M. The King; surgeon, Royal  
Westminster Ophthalmic Hospital.

### K.C.B. (Military)

Surgeon Vice-Admiral Robert William Basil Hall,  
C.B., O.B.E., M.R.C.S.  
Honorary physician to H.M. The King; medical  
director-general of the Navy.

### K.C.B. (Civil)

Arthur Salusbury MacNalty, M.D., F.R.C.P.  
Chief medical officer, Ministry of Health and Board  
of Education.

### Knights Bachelor

Lieut.-Colonel Charles Bickerton Blackburn, O.B.E.,  
M.D., Ch.M.  
Member of the council of the New South Wales  
branch of the British Medical Association.

James Sands Elliott, M.B., F.R.A.C.S.  
Honorary consulting surgeon, Wellington Hospital.  
For public services in the Dominion of New Zealand.

Cedric Stanton Hicks, M.Sc., M.B., Ph.D.  
Professor of human physiology and pharmacology at  
the University of Adelaide.  
For services to medical education.

Captain Hibbert Alan Stephen Newton, M.B., M.S.,  
F.R.C.S.

Member of the council and censor-in-chief, Royal  
Australasian College of Surgeons.

Major-General Cuthbert Allan Sprawson, C.I.E., M.D.,  
F.R.C.P., D.Litt.  
Honorary surgeon to H.M. The King; director-  
general, Indian Medical Service.

Lieut.-Colonel John Calderwood Strathearn, C.B.E.,  
M.D., F.R.C.S.  
Warden, St. John of Jerusalem Ophthalmic Hospital,  
Jerusalem; honorary consulting ophthalmic surgeon  
to the Government of Palestine.

Colonel Alfred Edward Webb-Johnson, C.B.E., D.S.O.,  
M.B., F.R.C.S.  
Surgeon to the Middlesex Hospital.

### C.B. (Military)

Air Vice-Marshal Alfred William Iredell, M.R.C.S.  
Honorary physician to H.M. The King; director of  
medical services, Air Ministry.

- Major-General Dudley Sheridan Skelton, D.S.O., M.R.C.S., D.P.H.**  
Honorary surgeon to H.M. The King; deputy director of medical services, Southern Command, India.  
**C.M.G.**
- Henry Harold Scott, M.D., F.R.C.P., F.R.S.**  
Director of the Bureau of Hygiene and Tropical Diseases, London School of Hygiene and Tropical Medicine.  
**C.I.E.**
- Lieut.-Colonel John Joseph Harper-Nelson, O.B.E., M.C., M.D., F.R.C.S.E., I.M.S.**  
Late principal and professor of medicine, King Edward Medical College, Lahore, Punjab.  
**C.B.E. (Military)**
- Group Captain Henry Ashbourne Treadgold, M.D., M.R.C.P.**  
Consultant in medicine, Royal Air Force.  
**C.B.E. (Civil)**
- Philip Douglas Oakley, M.R.C.S.**  
Director of medical and sanitary services, Sierra Leone.  
**O.B.E. (Military)**
- Lieut.-Colonel Norman Mello Fergusson, T.D., M.B., R.A.M.C. (T.A.)**
- Surgeon Captain Ernest MacEwan, M.R.C.S., R.N.**
- Major George Wishart Will, M.B., R.A.M.C.**  
Mental specialist, Southern Command, India.  
**O.B.E. (Civil)**
- Eldred Curwen Braithwaite, M.S., F.R.C.S.E.**  
Surgeon specialist, West African medical staff.
- Raj Kishore Kacker, L.M.S.**  
Medical superintendent, King Edward VII. Sanatorium, Bhowali, United Provinces.
- George Henry Masson, M.D., F.R.C.P.E.**  
Medical officer of health, Port of Spain, Trinidad.
- Lieut.-Colonel Anath Nath Palit, F.R.C.S.E., I.M.S.**  
Civil surgeon, Cuttack; superintendent, Orissa Medical School, Orissa.
- Charles Satchell Pantin, M.D., F.R.C.S.**  
Surgeon, Noble's Isle of Man Hospital.  
For public services in the Isle of Man.
- Walter Alexander Ramsay Sharp, M.B., Ch.M., F.R.C.S.E., F.R.A.C.S.**  
Surgical tutor, University of Sydney.  
For social welfare services in the State of New South Wales.
- Charles Gordon Timms, M.C., L.R.C.P.**  
Medical officer, Somaliland Protectorate.
- Alan Neil Yuille, M.B., F.R.C.S.**  
Government medical officer, Dubbo, State of New South Wales.  
**M.B.E. (Military)**
- Lieutenant Albert Edward Gomez.**  
Senior assistant surgeon, Indian Medical Department, British Military Hospital, Jhansi, India.
- Subadar Sampuran Singh.**  
Sub-assistant surgeon, Indian Medical Department, Indian Military Hospital, Quetta, India.
- Colin Thomas Symonds.**  
Assistant surgeon, Indian Medical Department, British Military Hospital, Belgaum, India.  
**M.B.E. (Civil)**
- Quirino Bonifacio De Freitas, M.R.C.S.**  
Government medical officer, British Guiana.
- Khan Bahadur Kershaw Dinshaw Khambatta, L.M.S., L.R.C.P., D.P.H.**  
Health officer, Poona City Municipality, Bombay.  
**Kaiser-i-Hind Gold Medal**
- Rustomji Bomonji Billimoria, M.D., J.P.**  
Private medical practitioner, Bombay.
- Lieut.-Colonel Sir James Reid Roberts, C.I.E., M.S., F.R.C.S., I.M.S. (ret.).**  
Special member of council, Dewas State (senior branch), Central India.
- Mrs. Ruth Young, M.B.E., M.B.**  
Women's Medical Service; principal, Lady Hardinge Medical College, Delhi.  
**Albert Medal in Gold**
- André John Mesnard Melly, M.C., F.R.C.S.E.**  
Awarded posthumously in recognition of the conspicuous gallantry that he displayed during the disorders in Addis Ababa in May, 1936.

## PUBLIC HEALTH

### A Year of Nutrition Centres in London

In his report<sup>1</sup> as school medical officer for the County of London Sir Frederick Menzies describes the nutrition centres as an attempt to blaze a new trail through uncharted territory. Five centres were established, one in each administration division, in May, 1935, for children who had been sent to voluntary general hospitals as under-nourished by the school-care committees, found there to have no disease, and sent away with nothing done. The children for the centres were selected partly by nomination of the school doctors, partly by nutritional surveys. In future selection will depend on the six-monthly weighing and measuring of all school-children which began in September, 1935.

In the northern division Dr. Margaret Hogarth explored the soundness of selecting children on the basis of failure to approach the normal weight for height, but more than half of these children although lanky were found to be healthy. This method was

therefore abandoned in favour of a special survey with the school doctor of children of poor appearance. Although most of the 303 children attended the centres more than once, a surprisingly large proportion failed to continue attendance, and emphasis is repeatedly laid on the value of the centre in educating parents. Dental caries was not commoner in these children than in others. Anæmia was quite uncommon, the average hæmoglobin content in the children at one centre being 92.5 per cent. Postural defects were often noted. Although it was impossible as a rule to get an accurate account of the child's diet, it was evident that ill-adjustment and ignorance of dietetic needs played a part. Many of the children came from bad houses where, as Dr. Cicely Peake remarks, parents have become hopeless from disappointment in their search for better accommodation. Dr. Alfred Elman emphasises the value of a happy home to the nutrition of a child. None of the physicians in charge is prepared to attribute ill-nourishment to any single and well-defined cause. Dr. L. W. Batten classifies presumed ætiological factors under five broad headings, with some overlapping: constitutional 24, environmental 32, food 8, present disease 8, past

<sup>1</sup> L.C.C. Annual Report of the Council, 1935, Vol. III., Part II. London: P. S. King and Son. No. 3196. Pp. 96. 1s. 6d.

disease 11. Dr. Evelyn Gourlay found three main causes for under-nourishment: (1) life under impoverished conditions; (2) ignorance of dietetic principles; (3) poor housing and overcrowding.

The recommendations for treatment made at the centres were carried out in a large proportion of cases, except that obviously housing improvement was generally impossible. Medical officers give their opinion frankly about the value and permanency of the experiment. Parents and children are benefitting says one, from the investigation and discussion of home difficulties. It is hard to believe, says another, that new light will be thrown on the nature and cause of malnutrition by the examination of any number of subnormal children. Another suggests that a clinic concerned purely with nutrition can hardly exist except as a welfare centre for school-children, but as such it has an important field for investigation and later of social service. Yet another doubts the value of tests and would concentrate on the practical problem of helping parents and children. Finally there is a suggestion that the work could be done as well at special sessions in the schools, but not adequately in the course of routine inspections. A divisional treatment organiser is confident that the most important factor in the work is the education of parents.

### Medico-Psychologist for L.C.C. Remand Home

The appointment is announced of Dr. J. D. W. Pearce as a part-time medico-psychologist at the Stamford House Remand Home under the London County Council. Dr. Pearce's duties, we understand, will be to examine all children admitted to the remand home as to their physical and mental state, with special reference to the delinquency with which the juvenile offender has been charged, and to submit reports to guide the magistrates of children's courts. Until the end of last year the remand home was situated at Ponton-road, Nine Elms-lane, and provided accommodation chiefly for children from the London area; in view of increasing numbers and the desire of other local authorities to share the home, a move was made to more suitable premises in January, 1936. The number of children passing through the home in 1930 was 785; in 1935 it was 2420. Hitherto the medical work has been done by a medical officer from the L.C.C. central public health department, with the assistance of a trained psychologist loaned from the London Child Guidance Clinic. Dr. Pearce will combine these duties, and the unification will reduce the number of examinations required. Reference will still be made to child guidance clinics when prolonged investigation is required.

## CORRESPONDENCE

### OÖPHORECTOMY AND CANCER OF THE BREAST

To the Editor of THE LANCET

SIR,—The interesting paper by Prof. Peter Paterson in your issue of June 20th and his reference to Sir George Beatson's cases prompt me to refer to an analysis of ninety-nine cases of inoperable carcinoma of the breast treated by oöphorectomy, which was published in vol. lxxxviii. of the *Transactions* of the Royal Medical and Chirurgical Society, 1905. In a certain number of these cases the operation was followed by very striking changes: pain was relieved, the general health improved, and the growths diminished in size or even disappeared. In all of them however, with one possible exception, the relief was only temporary, although in fifteen cases it persisted for more than twelve months, and four other patients had good health for over four years. The immediate results in Sir George Beatson's first two cases were very remarkable, but after a time the condition relapsed, and in the light of further experience the hope that this line of treatment might lead to a cure had to be abandoned.

It appears therefore that in some cases of carcinoma of the breast removal of the ovaries may have a pronounced though temporary effect on the growth, and it is significant that little or no improvement is to be expected in patients who are more than fifty years old.—I am, Sir, yours faithfully,

Harley-street, W., June 22nd.

HUGH LETT.

### INSULIN IN SCHIZOPHRENIA

To the Editor of THE LANCET

SIR,—With reference to your leading article in last week's issue (p. 1418) may I, as one who knows this therapy from practical experience both in Vienna and in this country, make a few observations? Surely there must be something to recommend a treatment that Prof. Pötl, who is the successor of Wagner-Jauregg, from personal observation extend-

ing from October, 1933, and relating to over 200 cases declares superior to every other method. Let it at once be said that Prof. Pötl was the first to proclaim that the innovation did not originate from his institution but from the Vienna physician Dr. Sakel, who was indeed fortunate in finding so magnanimous and unselfish a supporter. True, the methods of treatment for schizophrenia have been so numerous as to invoke scepticism against any new method, however well supported, but it is equally true that malarial treatment of G.P.I. was greeted with the same misgivings. The fact that early cases do so well with insulin therapy does not imply that the same patients would have made an equally good recovery without such treatment. After all, our vast mental hospital population of chronic schizophrenics have been early cases some time. If it is true that in this country there is a distressing increase in the number of patients suffering from schizophrenia,<sup>1</sup> the inference appears to be obvious. The recovery-rates with insulin therapy in Vienna and in Switzerland<sup>2</sup> considerably surpass the average expectation of spontaneous remissions, observed over long periods at the same institutions. I have stated elsewhere<sup>3</sup> that insulin treatment on closer acquaintance proves less deadly than at first sight, and that it is hypoglycæmia rather than shock that is the therapeutic agent. Quite a number of patients do well without reaching anything like the shock stage. It is only fair to state that Dr. Berze's criticism was, in his own words, based on general academic considerations rather than familiarity with the therapy in question. His article appeared a fortnight after a preliminary report, dealing with a dozen cases, was made from the Vienna clinic. Since then 200 cases have been treated at Vienna, apart from other centres.<sup>1</sup> The therapy is now being employed all over Europe and in Japan, and most reports are

<sup>1</sup> See Report of the Scottish Board of Control for 1935, p. 26.

<sup>2</sup> Müller, M.: Meeting of Swiss Neurologists and Psychiatrists, Freiburg, November, 1935.

<sup>3</sup> Münch. med. Woch., 1936, lxxxiii., 649.

encouraging. Those wishing to form their own opinion will welcome Dr. Sakel's recent report<sup>4</sup> on 102 cases, early and advanced, with details of their prognosis, response to treatment, and after-history.

I am, Sir, yours faithfully,

Edinburgh, June 22nd. H. PULLAR STRECKER.

### CHICKEN-POX AND SHINGLES

To the Editor of THE LANCET

SIR,—I saw a patient recently suffering from obvious shingles of the maxillary division of the fifth nerve. The vesicles were in two groups, one at the outer margin of the right eye, the other on the right side of the hard palate, and had been there for four days. I was asked whether the condition was infectious, and whether a boy who had been in contact with the case could be sent back to a boarding-school. There had been no known contact with any case of chicken-pox, and my reply was that the boy could safely return to school. Three days after my examination, and a week after the original herpetic eruption, the patient developed chicken-pox. Now although the relationship between chicken-pox and shingles has long been suspected, though not proved, this case raises two points, one academic, one practical. In the first place, if the virus of the two conditions is the same except for its distribution, the incubation period must be different; in the second place, are we to put in quarantine all contacts with shingles, or should we be prepared to burst the bubble reputation and take a chance? In view of the fuss, bother, and excitement occasioned by this particular case in the heart of a mother, and the mind of a housemaster, an authoritative opinion on the latter point would be welcome.

I am, Sir, yours faithfully,

Brecon, June 20th.

DAVID KYLE.

### TREATMENT OF PHLEBITIS IN VARICOSE VEINS

To the Editor of THE LANCET

SIR,—In your issue of May 2nd Mr. Payne writes that my viewpoint is contrary to current teaching and to his own opinions. In view of the fact that I propose a new method of attack on these rebellious disorders, it should be apparent that the views proposed would refute older teachings. He asks whether clinical experience supports my contention that the conservative treatment of phlebitis often ends in a permanently damaged extremity. I would refer him to an article I have just written (Lymphedema occurring with Varicose Veins: Treatment by Injection, Arch. Derm. and Syph., April, 1936) describing many cases of extremities damaged from untreated phlebitis, coupled with histological and clinical proof. It is impossible to overlook the connexion between phlebitis and chronic lymphangitis resulting in lymphoedema. Other physicians besides myself who see these legs constantly in practice realise that there are many thousands of sufferers from lymph legs who might have been saved with more radical treatment at the outset.

Mr. Payne is unwilling to accept my concept of latent phlebitis, stating that the absence of tenderness, thrombosis, and hyperthermia makes the term phlebitis inapplicable. This objection is surprising because for many years clinicians have so classified a great many latent infections and clinical entities. I might mention a few, such as chronic tuberculosis, chronic salpingitis, and chronic tonsillitis. To deny

the existence of an infection because of the absence of clinical signs is dangerous, especially in varicophlebitis, where disastrous results may follow routine injection. Mr. Payne uses injections after an arbitrary period of six months, but does not explain his reasoning for the determination of this lapse of time. He overlooks the significance of migrating reactions, and attempts with theoretical objections to break down the painstaking clinical and laboratory framework on which the modern treatment of this disorder is based.

In any attempt to disprove the more radical approach to this problem may I suggest the following investigations:—

1. Cultural studies of excised portions of varicose veins.
2. Blood culture studies of patients in whom flare-up reactions are obtained during treatment.
3. Studies of the antibody formation in the blood of patients undergoing varicose vein therapy, especially those showing migrating reactions.
4. Histological sections of subcutaneous tissues which are discoloured and hardened in cases of varicose veins.

If Mr. Payne will retrace the path taken by previous investigators he will, I think, arrive at the same conclusion—namely, that phlebitis in varicose veins is the starting-point of a pernicious cycle which results in damaged extremities and should be attacked immediately by the method I have described.

I am, Sir, yours faithfully,

H. I. BIEGELEISEN.

Madison-avenue, New York, June 12th.

### IONISATION FOR HAY-FEVER

To the Editor of THE LANCET

SIR,—I should be grateful if you would allow me space in your columns to disclaim responsibility for the publicity given to my name in the press this week in connexion with a particular form of treatment for hay-fever. In my paper published in the *Practitioner* in May of this year I gave full credit to Mr. Philip Franklin for introducing me to this method of treatment in a communication he made to the *British Medical Journal* in 1931. The use of zinc sulphate for ionisation in the nose is of course not new. With Mr. Franklin I deplore the exaggerated claims made in the press. In my paper the claim I made was that "on theoretical and practical grounds intranasal ionisation of zinc sulphate is a justifiable and valuable method of treating hay-fever and vasomotor rhinorrhoea." Mr. Franklin's own experience and my own further observations lead me to believe that this is no exaggeration.

In your admirable survey of the position at the moment you state, Sir, that ionisation "is evidently not appropriate for slight cases that can be relieved by simpler means." With all respect, I must disagree with this statement. It is impossible to go fully into my reasons for this here; briefly, in my own opinion, the use of sprays and ointments (especially those containing ephedrine) in vasomotor rhinorrhoea should be abandoned. The reactionary congestion which they produce is far worse than the initial discomfort. I am, Sir, yours faithfully,

Park-lane, W., June 19th.

CLIVE SHIELDS.

ROYAL SURREY COUNTY HOSPITAL, GUILDFORD.—On June 13th the Duchess of Northumberland opened the new wards at this hospital providing 32 new beds, 16 for men and 16 for women. The extension has cost £13,500, of which £10,000 was the gift of an anonymous donor. The hospital is very crowded and there is a waiting-list of more than 250.

## PARLIAMENTARY INTELLIGENCE

### UNEMPLOYMENT AND MALNUTRITION

On June 22nd, in the House of Commons, the vote for the salaries and expenses of the Unemployment Assistance Board was considered in Committee.—Mr. LAWSON, who moved to reduce the vote by £100, asked if the 12 months' administration of the Board had been satisfactory to the House of Commons and the country. The fact, he said, still remained that two out of every three men who offered themselves for the Army were physically unfit, and the Government made no secret of the fact that many of the recruits came from areas where unemployment was bad. After 12 months' operation of the means test in Durham, a commissioner was put in charge. When he began in 1932 10,000 children were receiving milk on medical certificates in the schools. When he finished there were 20,000 receiving milk on the charge of the local authorities. Twelve months later there were 25,000 children receiving milk in the schools. Doctors were really alarmed at the state of the children in the area compared with other areas. He was talking to a medical man at the week-end, who told him that 75 per cent. of the children who were sent to the isolation hospital in his (Mr. Lawson's) own area were suffering from malnutrition. That was the case all over the country. The Minister of Labour and the Board could not blink the fact that during the 12 months the Board had been in operation they not only had not touched the edge of the problem affecting work, but that the physical condition of the people in the distressed areas was getting worse. The doctor to whom he had referred had told him that it was almost impossible to deal with some people; they ought to get better, but it was hopeless trying to deal with them because they were hopeless themselves.—Miss HORSBROUGH said that in a great many cases applicants for assistance had far too little knowledge of what was the best food to give the most nourishment. There ought to be, especially where there was a small income, further education as to the best way that income could be used. One heard from medical officers that if they could—she did not think they could, because it would mean interfering with the individual—guide better the food which was chosen, there would be less malnutrition. The subject of nutrition should be studied by all interested in the people, and poor persons who had little to lay out ought to have much more guidance.—Mr. ERNEST BROWN, Minister of Labour, said that in all the years during which a test of need had been applied no one had yet discovered an effective way of applying a test except on a household basis. He intended to make it his business, when the new regulations were presented to the House of Commons, to see that all the information needed was given so that Members might form a judgment on the proposals. The discussion had shown that the debates tended to get out of perspective and individual cases seemed to occupy the whole field, while little attention was paid to the magnitude of the work done by the Board in handling this complex question. Far from the district administration being a soulless bureaucratic thing, it was immensely superior to anything that had ever been done for the unemployed.—After further debate, Lieut.-Colonel MUIRHEAD, Parliamentary Secretary to the Ministry of Labour, said it had been the aim of the Unemployment Assistance Board to introduce a certain amount of elasticity in the administration which was thoroughly desirable. Their report said that every applicant was a separate human being with his own needs and environment, and the Board had throughout encouraged and instructed its officers to take this view of each case. This was shown to be so by the fact that in no less than 20 per cent. of the cases the officers of the Board had used their authority to grant allowances above the normal rate. With regard to welfare work, the Board was coöperating

with the Ministry of Labour and the commissioners for the special areas and with such bodies as the Land Settlement Association.

### NOTES ON CURRENT TOPICS

In the House of Lords on June 23rd the Road Traffic (Driving Licences) Bill was read the third time and passed, and the Public Health (Drainage of Trade Premises) Bill passed through Committee.

#### Exemption from Duty of Invalid Carriages

On June 17th in the House of Commons Mr. KIRKPATRICK moved a new clause in the Finance Bill providing for the exemption of invalid carriages from duty imposed under the Finance Act, 1920, on licences for mechanically propelled vehicles.—Mr. W. S. MORRISON, Financial Secretary to the Treasury, said that this new clause was one that could be accepted. At present the duty on invalid carriages was only 5s. a year and as there were 1600 of these carriages, as far as the Government could tell, the amount of duty which would be lost by accepting the new clause would be some £400 a year.

### QUESTION TIME

WEDNESDAY, JUNE 17TH

#### Medical Practice in Palestine

Mr. GRAHAM WHITE asked the Secretary of State for the Colonies the nature of the representations submitted by the Arabs in Palestine to the Mandates' Commission.—Mr. ORMSBY-GORE replied: Representations have been submitted to the Permanent Mandates Commission on behalf of the Palestine Arab Party, on the subjects of the form of Government in Palestine, Arab education, Jewish immigration, land policy, and the Hahsh Concession, and on behalf of the (Arab) National Medical Association on the number of Jewish medical practitioners in Palestine.

#### Staff Hours at Perth Asylum

Mr. MATHERS asked the Secretary of State for Scotland whether he had considered the petition by the criminal lunatic asylum staff at Perth, complaining of long hours of duty and irregular meal-times; and what action he intended to take to remedy these grievances.—Sir GODFREY COLLINS replied: After consultation between the Governor and the staffs a revised scheme of duties proposed by the staffs was introduced experimentally on April 27th. The working of this scheme will be kept under review and any suggestions made by the staff for alteration will be duly considered. No suggestion for change has so far been made.

#### "Incapable of Work"

Mr. JOSEPH HENDERSON asked the Minister of Health whether he was aware that under the National Health Insurance Act a panel doctor had to certify an individual as fit for work as soon as he was no longer totally incapacitated, whilst some employers, such as railway companies, refused to allow an individual to resume employment until he was fully restored to health, with the result that he was deprived both of wages and national health insurance benefit; and whether, therefore, he would consider the desirability of amending the Health Insurance Acts to provide benefit to an insured person until he was fit to resume his normal employment.—Mr. SHAKESPEARE replied: Insurance medical practitioners and approved societies have been advised that an insured person should be regarded as incapable of work within the meaning of the National Health Insurance Acts if he is unfit to follow his ordinary occupation, but it appears probable that he will soon be fit to do so. Cases of the kind referred to by the hon. Member should not, therefore, arise.

#### Abnormal Maternity Cases

Mr. LEONARD asked the Minister of Health if he was aware that, following the decision of Rochdale doctors to send all abnormal maternity cases to hospital, the

maternal death-rate had been reduced by 60 per cent.; and if he would consider the desirability of urging an extension of this practice.—Mr. SHAKESPEARE replied: My right hon. friend is aware that there has, happily, been a reduction in the maternal mortality-rate in Rochdale which is, he is advised, due to the operation of a number of factors. It has been the practice of my department for many years to urge the provision of hospital beds for abnormal maternity cases.

Mr. LEONARD: Is the hon. gentleman aware that the practice referred to in the question is universal in Holland, where there is an exceptionally low maternal death-rate and, if so, does he not consider it desirable to adopt the practice widespread in this country?

Mr. SHAKESPEARE: I think it is universal in this country as well.

#### R.A.F. Flying near Colindale Hospital

Mr. McENTEE asked the Under-Secretary of State for Air whether he was aware of the serious consequences to patients of the Colindale Hospital arising from the Royal Air Force flying and searchlight operations in the vicinity of the hospital, sometimes proceeding for 12 hours and as late as midnight, and especially near the west side of the aerodrome where the Colindale and Redhill hospitals were situated; that the hospital inmates needed rest and quietness; and that the medical staff had sometimes to suspend their stethoscopic work because of the overhead noise; and whether he would take steps to secure the minimisation at the earliest possible moment of the activities complained of.—Sir P. SASSOON replied: I am aware that complaints have been made in regard to the flying of Royal Air Force aircraft in the vicinity of the Colindale Hospital and the Air Ministry has already issued instructions that pilots are to avoid as far as possible taking off and coming in to land over the hospital, particularly at night. I hope that these steps will materially reduce the inconvenience. At the same time it will, I am sure, be appreciated that the Royal Air Force expansion programme inevitably involves a considerable increase of flying activity, and despite the restrictions placed on pilots a certain amount of inconvenience is unavoidable if the efficiency of the Air Force for defence purposes is to be maintained.

THURSDAY, JUNE 18TH

#### Medical Practitioners and Poison-Gas Treatment

Mr. EMMOTT asked the Home Secretary what facilities had been provided in the London area for doctors wishing to obtain instruction in the treatment of poison-gas cases.—Mr. GEOFFREY LLOYD replied: The General Medical Council and the British Medical Association have been consulted on this matter, and arrangements for giving instruction to medical practitioners in the treatment of poison-gas cases are under consideration. The Air Raid Precautions Department are accumulating stores of respirators and other means of protection for all public air raid precautionary services.

Mr. CARTLAND asked the Home Secretary what steps were being taken to instruct householders as to the methods they could adopt to render their rooms proof against poison gas in the event of air raids.—Mr. LLOYD replied: A handbook on the precautionary measures which members of the public should take in the event of air raids is in an advanced state of preparation.

#### Nystagmus Patients and Workmen's Compensation

Mr. SHORT asked the Home Secretary whether he was aware that many miners in Yorkshire suffering from accidents and industrial diseases and subject to the provisions of the Workmen's Compensation Acts were frequently certified as being fit for work by the indemnity company's doctor but were refused employment when making application to their employers; and whether this aspect would be the subject of consideration of the departmental committee on workmen's compensation.—Sir JOHN SIMON replied: I am aware that in the area named miners who have been in receipt of compensation for nystagmus may find this is an obstacle to re-employment, and this aspect of the matter is being considered by the Departmental Committee in connexion with their inquiry into compensation for that disease.

Mr. T. SMITH: Is the right hon. gentleman aware that this practice is not confined to those who have suffered from nystagmus, but affects also many who have recovered, or partially recovered, from accidents? Has the general question been considered by the department?

Sir J. SIMON replied: I shall be obliged if the hon. Member will communicate with me about other cases, because I should like to learn how much evidence there is of this practice. It would be possible to enlarge the inquiry in case of need.

#### Anti-Gas Instruction Centres

Captain PLUGGE asked the Home Secretary what was the estimated annual output of trainees from the new anti-gas school at Eastwood Park operated by the air-raid precautions department of the Home Office; and whether consideration had been given to the desirability of having additional schools in other parts of the country.—Mr. GEOFFREY LLOYD replied: It is hoped that, under present arrangements, the output of the Civilian Anti-Gas School at Falfield in a full year would be in the region of 600 fully trained instructors in addition to the provision of short courses for some 250 doctors and other specialists. It has been decided that this output shall be increased and the steps by which this may be effected are being examined.

MONDAY, JUNE 22ND

#### The Problem of Nutrition

Mr. CARTLAND asked the Minister of Health what steps his advisory committee on nutrition were taking to collect sufficient data to enable the Government to formulate a policy for dealing with the problem of nutrition.

Mr. LENNOX-BOYD asked the Minister of Health whether, subsequent to the Bishop Auckland potato scheme, any further experiments had been carried out with a view to ascertaining the possibilities of making supplies of nutritious food available at reduced prices to the unemployed.

Mr. SANDYS asked the Minister of Health whether his attention had been drawn to the fact that the average expenditure on food of 4,500,000 persons in this country does not exceed 4s. per week per head; and whether the advice of his medical advisers indicated that this was sufficient to maintain health and working capacity.—Mr. SHAKESPEARE replied: My right hon. friend is aware that an estimate of average expenditure on food has been made to the effect stated, but he is advised that the data on which it is based are not sufficient to justify positive conclusions. The whole question of the adequacy of diets is now being actively examined by the Advisory Committee on Nutrition, who have before them all the available statistical information, including the results of the Bishop Auckland experiment, which my right hon. friend understands the Potato Marketing Board do not propose to repeat this season. The Committee have, however, recommended the departments concerned to collect family budgets and undertake dietary surveys and to obtain information as to the distribution of weekly earnings and family incomes. My right hon. friend, the Minister of Labour, is about to give effect to the recommendation as to family budgets in his forthcoming inquiry as to the cost of living index, and the other matters are now under consideration.

TUESDAY, JUNE 23RD

#### Military Hospital at Radford

Mr. GUY asked the Secretary of State for War if he could give the reasons for the delay in proceeding with the scheme for a new military hospital at Radford.—Mr. DUFF COOPER replied: The provision of the new military hospital at Radford is delayed because of other more urgent building services which must take priority.

#### Patent Medicines

Mr. DAY asked the Minister of Health whether he proposed to introduce legislation to give effect to the recommendations of the select committee on patent medicines.—Mr. SHAKESPEARE replied: No, Sir. The Government have no present intention of introducing legislation for this purpose. As the hon. Member is aware, the subject was recently debated on a Private Member's Bill, which failed to obtain a second reading.

## MEDICAL NEWS

## University of Oxford

Mr. William Stephenson, M.Sc., research assistant and supervisor of the research students' psychology department at University College, London, has been appointed assistant director of the institute of experimental psychology.

## University of Cambridge

On June 23rd the following degrees were conferred:—  
*M.D.*—H. J. Burrows, C. L. Potts, and H. C. Stewart.  
*M.B., B.Chir.*—C. J. Gordon and W. H. Valentine.  
*M.B.*—J. B. Tracey.  
*B.Chir.*—\*W. A. Briggs, \*W. T. Cooke, C. E. Elliott, and H. S. H. Gilmer.

\*By proxy.

## University of London

*Centenary Celebrations.*—The main event in the programme is a reception to be held at the university, South Kensington, on June 29th, when delegates will present congratulatory addresses and honorary degrees will be conferred on the following distinguished men (13 British and 6 foreign): Sir William Bragg, P.R.S., Mr. S. A. Courtauld, Mr. P. M. Evans, LL.D., The Archbishop of Westminster, Sir Joseph Larmor, F.R.S., Dr. J. W. Mackail, O.M., Sir George Newman, Sir Charles Peers, Lord Snell, Prof. G. M. Trevelyan, O.M., Mr. H. G. Wells, Dr. R. Vaughan Williams, O.M., Lord Wright, Don Ramón Perez de Ayala, and Prof. Max Planck; and in absentia Mr. Justice Benjamin N. Cardozo, Prof. Albert Einstein, Prof. Johan Hjort, and Dr. Emile Legouis. In the evening there will be a university dinner at the Grosvenor House Hotel, at which the Chancellor, the Earl of Athlone, will preside, and among the other evening festivities arranged are a Ball given by the Worshipful Company of Drapers at the Drapers' Hall, on June 30th; receptions at Lancaster House, St. James's, by H.M. Government on July 1st, and at the County Hall, Westminster, by the London County Council on July 3rd; and conversaciones at Bedford College for Women and at St. Bartholomew's Hospital medical college on July 2nd. A special service will be held at St. Paul's Cathedral on July 1st preceded by a procession up Ludgate-hill and followed by a lunch given by the Lord Mayor and Corporation of the City of London in the Guildhall. Garden parties will be held to-day, Saturday, at the Royal Holloway College and on July 2nd at King's College of Household and Social Science. On July 3rd a visit will be paid to the new buildings of the university now being erected in Bloomsbury when the architect, Mr. Charles Holden, will be in attendance.

Mr. H. L. Eason has been re-elected vice-chancellor for the year 1936-37.

The title of reader in neurological anatomy in the university has been conferred on Miss U. L. Fielding, M.B. Sydney, in respect of the post held by her at University College.

Miss Fielding has been on the staff of University College since 1923, having formerly been a demonstrator of anatomy in Sydney, and held resident hospital posts there. In order to make a comparative anatomical study of the nervous system she sought an opportunity to work in the department of Sir Grafton Elliot Smith at University College, where she was appointed demonstrator in anatomy and later lecturer in neurology. During the session 1928-29 she was absent on leave, and acted as professor of neuro-anatomy and histology in the American University of Beirut. Miss Fielding has collaborated with Mr. A. S. Parkes, F.R.S., and Prof. F. W. R. Brambell in a series of studies of the ovary and with Prof. Gregor Popa on the vascular connexions of the pituitary body.

Mr. W. V. Mayneord, D.Sc., has been appointed to the university readership in physics tenable at the Royal Cancer Hospital (Free).

Dr. Mayneord was born in 1902. He graduated B.Sc. with honours from the University of Birmingham in 1921, and became M.Sc. in 1922 and D.Sc. in 1933. From 1922-24 he was engaged in research work. In 1924 he was appointed demonstrator in physics at St. Bartholomew's Hospital medical college, in 1927 physicist to the radiological department of the Royal Cancer Hospital, and since 1936 he has also been acting head of the physics department at the hospital. In 1932 he gained the Röntgen award and in the following year he became a Fellow of the Institute of Physics. He has published papers in the *Proceedings* of the Royal Society and in medical, radiological, and chemical journals.

## University of Bristol

The dissertation of Bessie V. F. Dawkins has been approved for the degree of M.D.

## University of Glasgow

Dr. John Shaw Dunn has been appointed to the chair of pathology in the university in succession to Sir Robert Muir, F.R.S.

Dr. Shaw Dunn was born in 1883 at Kilmarnock and educated at Kilmarnock Academy, Glasgow High School, and Glasgow University, where he graduated M.A. in 1901. Four years later he took his M.B. degree with honours and in 1912 his M.D. degree. After graduation he acted as assistant pathologist to the Western Infirmary, and continued studying and teaching pathology as assistant to the professor of pathology until 1914 when he was appointed lecturer in clinical pathology. During the war he served with the R.A.M.C. and received the rank of brevet major. In 1919 he was appointed to the chair of pathology at Birmingham, and three years later to Manchester, where he became M.Sc. in 1929. He took up his present position of Notman professor of pathology at St. Mungo's College, Glasgow, in 1931. His publications include many articles on pathology with special reference to renal disease.

On June 17th the honorary degree of LL.D. was conferred on Dr. T. H. Bryce, emeritus professor of anatomy in the university, and on Sir Leonard Rogers. The following degrees were also conferred:—

*M.D.*—J. F. Smith (with honours), A. A. MacKellie (with high commendation), George Krasner (with commendation), Alexander Maclean, and J. A. Ronghead.

## University of Sheffield

Dr. A. E. Barnes, lecturer on medicine in the university and Semon hon. physician to the Royal Infirmary, Sheffield, has been appointed to the chair of medicine in succession to Prof. A. E. Naish.

Dr. Barnes received his medical education at Sheffield and graduated in 1903 when he took a London degree in medicine. After holding resident appointments at the Royal Infirmary and Royal Hospital, Sheffield, he was awarded the research scholarship of the British Medical Association in 1907. In the same year he took the membership of the Royal College of Physicians and a year later he took the medical degree of the newly constituted University of Sheffield. He then became medical tutor and lecturer on materia medica. During the war Dr. Barnes served at the Sheffield base hospital and afterwards at Salonika, where he was in charge of the medical side of the hospital arrangements. Returning to Sheffield he resumed his position on the medical side of the Royal Infirmary, and in 1921 was elected F.R.C.P. Lond. He also served on the Sheffield insurance committee. His contributions to medical journals include an article on simple methods of diagnosing diseases of the stomach published in our columns.

The following were appointed members of the medical faculty: Sir Arthur Hall, Dr. A. E. Barnes, Dr. H. E. Harding, Dr. C. G. Imrie, Dr. M. A. MacConaill, Dr. Dakin Mart, Dr. E. F. Skinner, Dr. A. G. Yates, Mr. R. St. L. Brockman, and Mr. J. E. Stacey.

## Order of St. John of Jerusalem

The following promotions in and appointments to the Venerable Order of the Hospital of St. John of Jerusalem have been sanctioned by the King:—

*As Knight of Grace.*—Lieut.-Col. W. B. Cockill, T.D., M.D. Mr. W. C. Bentall, O.B.E., and Wing-Commander H. R. G. Poate, F.R.C.S.

*As Commander.*—Dr. J. J. Huey, Dr. M. C. O. Hurly, Dr. E. Llewellyn, Dr. S. Williams, Dr. W. E. Thomas, O.B.E., and Dr. J. M. Wilson.

*As Officer.*—Dr. C. Reid, O.B.E., Dr. T. Bell, Dr. S. T. Rowling, Dr. A. Anderson, Colonel J. A. H. Sherwin, M.D., Dr. P. J. Kelly, C.B.E., Mr. R. F. Moore, O.B.E., F.R.C.S., Dr. F. E. Bendix, Dr. F. J. Green, M.C., Dr. R. B. Milne, and Dr. E. M. Griffith.

*As Associate Officer.*—Colonel D. Horwich, O.B.E., M.R.C.S., and Dr. H. F. Khalidi.

*As Serving Brother.*—Dr. J. A. Kennedy, Dr. L. J. Dunstone, Dr. H. Scholefield, Dr. C. Thompson, Dr. J. L. McK. Brown, Dr. C. C. Hargreaves, Dr. R. M. H. Walford, Dr. H. C. Sinderson, M.V.O., O.B.E., Dr. W. Vickers, D.S.O., Dr. E. Hoerman, Dr. J. P. J. Jenkins, and Dr. C. G. MacKay.

*As Associate Serving Brother.*—Dr. S. P. Swami and Dr. G. S. Vazkar.

## Society for the Provision of Birth Control Clinics

A lecture on the theory and practice of contraception will be given to medical practitioners and medical students by Dr. Gladys Cox on Friday, July 24th, at 6 P.M. at the Walworth Women's Welfare Centre, 153A, East-street, London, S.E. Practical demonstrations will be given on Friday, July 31st, at 6 P.M. and at 7 P.M. by Dr. Lynette Hemmant. Further information may be had from the secretary of the society.

**National Conference on Maternity and Child Welfare**

The National Association for the Prevention of Infant Mortality has organised a national conference which will be held in Liverpool on July 1st, 2nd, and 3rd, under the presidency of Mr. Geoffrey Shakespeare, Parliamentary Secretary to the Ministry of Health. On the first day of the meeting Dame Janet Campbell, Prof. A. Leyland Robinson, Dr. Katharine Hirst, and Miss E. Alden will open a discussion on the promotion of maternal welfare in relation to child health, and Dr. Charlotte Douglas will be the first speaker in a debate on maternal welfare and the public. On July 2nd Dr. Margaret Bjorkegren will speak on the education of parents through day nurseries and nursery schools, and Dr. N. B. Capon and Mr. Bryan McFarland on the importance of co-operation between maternity and child welfare services and the specialist health services. On the last day of the meeting Dr. C. L. C. Burns will be one of the speakers in a discussion on parents and substitute parents, and Dame Louise McIlroy and Prof. S. J. Cowell will open a discussion on antenatal nutrition. During the conference visits will be paid to municipal and voluntary maternity and child welfare institutions. Further information may be had from the secretary of the association, Carnegie House, 117, Piccadilly, London, W.1.

In connexion with this conference the maternity and child welfare group of the Society of Medical Officers of Health is holding a meeting in Liverpool on July 3rd and 4th. The annual general meeting will be held at 5.30 P.M. on July 3rd when Dr. George M'Gonigle will give his presidential address. On the following day papers will be read by Dr. R. E. Roberts (X rays and pelvimetry); Dr. J. Burke (amniography); Dr. R. J. Minnitt (gas and air analgesia in midwifery); and Mr. C. M. Marshall (certain aspects of obstetrics). In the afternoon members will visit Alder Hey Children's Hospital where Dr. Cecile Asher will read a paper on nutrition in infancy. Dr. R. E. Bell, maternity and child welfare department, 67, Dales-street, Liverpool, 2, is making arrangements for the meeting.

**Society of Apothecaries of London**

The livery dinner of this society was to have been held on Feb. 25th but it was cancelled on account of the death of the late King. Opportunity was therefore taken on June 23rd to combine court and livery dinners. The date was happily chosen and King Edward's birthday was marked by sending him a telegram offering loyal greetings of liverymen and guests. A reply expressing the King's thanks was received in the course of the dinner. —The approaching centenary inspired the chief toast of the evening, that of the University of London, and the principal guests included Mr. H. L. Eason, vice-chancellor of the university, Lord MacMillan, chairman of the court, Sir Edwin Deller, principal, Prof. Sidney Luxton Loney, chairman of convocation, Prof. L. N. Filon, and the Rev. Canon J. A. Douglas.—Sir William Willcox, master of the society, proposing this toast, said that that was the first occasion on which the university had been entertained in connexion with its centenary. He believed that the awakening a century ago of the national conscience to the urgent need for a revolution in health, hygiene, and education was responsible for the genesis of the university. In the last decade, however, they had seen greater advances than ever before and he was afraid that the pace might be too fast to be healthy; perhaps they could afford to rest on their laurels. In these democratic days, he concluded, the university had shown itself to be the poor man's university, and from its foundation it had grown by evolution to the most efficient in the world. —Mr. Eason, responding, claimed that the university, the largest in Great Britain, had more than a quarter of the country's students. He was proud that the funds for the new site at Bloomsbury had been obtained before they had begun to build. In granting medical degrees the university, he said, had no desire or intention to supplant the ancient licensing bodies. On the contrary, it envied them their antiquity and it had even been criticised because so small a proportion of the registered medical students had graduated. He felt sure that if the other faculties had alternative and more convenient

and economical portals similar to those of medicine, they would be affected in the same way.—Dr. A. P. Gibbon, senior warden, proposed the health of the Livery. He appealed for funds to undertake essential repairs to the hall's structure.—Mr. V. Warren Low, in replying, compared the place given to organotherapy and patent medicines by certain of the profession to that given to the stuffed alligator in the old apothecary's shop.

**West London Medico-Chirurgical Society**

The fifty-fourth annual banquet of this society will be held at the Trocadero Restaurant, Piccadilly, on Wednesday, July 8th, at 8 P.M. The hon. secretary's address is 128, Harley-street, London, W.1.

**Boscombe Hospital**

Lady Malmesbury has opened the new extension to the nurses' hostel at this hospital, which is the first part of a £50,000 extension scheme. The building contains an attractive recreation-room and a well-stocked library. On the top floor are 83 bedrooms and the floors are sound-proof. A new operating theatre block and wards are at present being built.

**Post-graduate Courses in Berlin**

International post-graduate courses are to be held in Berlin on the following subjects: throat, nose, and ear diseases (Sept. 28th–Oct. 10th); pædiatrics (Oct. 19th–24th); malignant diseases (Oct. 19th–26th); vitamins and hormones (Oct. 26th–31st); tuberculosis (Nov. 2nd–7th); homœopathy (Oct. 12th–Nov. 6th). Monthly courses in all the special departments of medical science, including practical work, will also be held. Particulars may be had from the information bureau of the Kaiserin Friedrich-Haus, Robert Koch-Platz 7, Berlin, N.W.7.

**British Social Hygiene Council**

Addressing the annual meeting of the Council, held at the London School of Hygiene and Tropical Medicine on June 17th, Sir Kingsley Wood, Minister of Health, said that in this country the view had been taken that any element of compulsion in the treatment of venereal disease was likely to defeat its own object. Better results might be expected if the arrangements for treatment were based on the voluntary principle and the conditions under which treatment was provided were such as to encourage persons to make use of them. Treatment was therefore provided free, it was given under conditions of secrecy, and the treatment centres were open to all comers irrespective of their place of residence. Results generally, he said, were improving. There was a more general realisation of the importance of seeking medical advice at an earlier date. Persons attending the treatment centres continued their attendance for a longer period, and an increasing number took advantage of the facilities for diagnosis now available. The incidence of syphilis was declining: recent infections dealt with at the treatment centres in 1935 were just under 6000 as compared with something over 9000 in 1925, while the mortality of infants certified as due to the disease in 1934 was less than one-half what it was in 1924 and about one-sixth of that in 1917. Renewed efforts were, he thought, desirable in two directions. Women should be encouraged to attend the treatment centres, and to bring children for observation and treatment. No new medical discovery was needed to rid the community of congenital syphilis. There was need too for the development of work in rural areas.

**Appointments**

GARFIELD, G. H., M.B. Wales, has been appointed Medical Superintendent of the Penrhilyn Infirmary, Neath.  
GREGORY, J. C., M.R.C.S. Eng., D.C.O.G., Hon. Assistant Medical Officer to the West Herts Hospital, Hemel Hempstead.  
JONES, E. C. B., M.Ch. Orth. Liverp., F.R.C.S. Eng., Surgeon-in-Charge of the East Suffolk and Ipswich Hospital.  
PEARCE, J. D. W., M.D., M.R.C.P. Edin., D.P.M., Medico-psychologist, Stamford House Remand Home, L.C.C.  
SHARPE, B. E. A., M.B. Glasg., D.P.H., Assistant Medical Officer in the School Service of the L.C.C.  
TOWNSLEY, G., M.D. Belf., Resident Surgical Officer at St. Bartholomew's Hospital, Rochester.

## Vacancies

- For further information refer to the advertisement columns
- All Saints' Hospital for Genito-urinary Diseases, Austral-street, West-square, S.E.**—Hon. Pathologist.
- Battersea General Hospital, Battersea Park, S.W.**—Hon. Gynaecologist, Ophth. Surgeon, and Ear, Nose, and Throat Surgeon.
- Bedford County Hospital.**—First H.S., at rate of £155.
- Birmingham, Erdington House.**—Jun. Asst. M.O., at rate of £200.
- Birmingham and Midland Eye Hospital.**—H.S., at rate of £130.
- Blackburn Royal Infirmary.**—Res. H.P., £175.
- Bolingbroke Hospital, Wandsworth Common, S.W.**—Hon. Surgeon. Also Hon. Surg. to Ear, Nose, and Throat Dept.
- Bolton Royal Infirmary.**—H.S., £125.
- Brighton Borough Infectious Disease Hospital and Sanatorium.**—Sen. Res. M.O., £450.
- Brighton, Royal Sussex County Hospital.**—Cas. H.S., £120.
- Bristol Royal Infirmary.**—Res. Med. appts., at rate of £150, £100, and £80.
- British Postgraduate Medical School, Ducane-road, W.**—H.P.
- Burnley, Municipal General Hospital.**—Jun. Res. M.O., £150.
- Burton-on-Trent General Infirmary.**—H.S., £150.
- Cambridge, Addenbrooke's Hospital.**—H.S., at rate of £130.
- Central London Throat, Nose, and Ear Hospital, Gray's Inn-road, W.C.**—Hon. Second Asst. in the Out-patient Dept.
- Charing Cross Hospital, W.C.**—Hon. Asst. Radiologist.
- Chester City (Public Assistance) Hospital.**—Jun. Res. M.O., £200.
- Chesterfield and North Derbyshire Royal Hospital.**—Cas. O. and Fracture H.S., at rate of £200. Also H.S. to Ophth. and Ear, Nose, and Throat Depts., at rate of £150.
- Cobham, Surrey, Schiff Home of Recovery.**—Res. Surg. O., £200.
- Colchester, Essex County Hospital.**—Asst. H.S., £120.
- Connaught Hospital, Walthamstow, E.**—H.S. and Cas. O., each at rate of £100.
- Doncaster Royal Infirmary.**—H.P., £175.
- Doncaster Royal Infirmary and Dispensary.**—H.S. to Eye and Ear, Nose, and Throat Dept., £175.
- Ealing, King Edward Memorial Hospital.**—Sen. Asst. Res. M.O., at rate of £200.
- Eastbourne, Princess Alice Memorial Hospital.**—Res. H.S., £150.
- Edmonton, North Middlesex County Hospital.**—Res. Asst. M.O., £400. Also Jun. Asst. Res. M.O., at rate of £250.
- Evelina Hospital for Sick Children, Southwark, S.E.**—H.S., at rate of £120.
- Golden-square Throat, Nose, and Ear Hospital, W.**—Hon. Asst. Surgeon.
- Great Yarmouth General Hospital.**—H.S., at rate of £140.
- Greenwich Metropolitan Borough.**—Tuber. O. for Council's Dispensary and Deputy M.O.H., £750.
- Harrogate Royal Bath Hospital.**—Res. M.O., £156.
- Hastings, Royal East Sussex Hospital.**—Jun. H.S., at rate of £150.
- Hospital for Consumption and Diseases of the Chest, Brompton, S.W.**—H.P., at rate of £50.
- Hull Municipal Maternity Home and Infants' Hospital.**—Jun. Res. M.O., at rate of £100.
- Ilford, King George Hospital.**—Hon. Dermatologist.
- Indian Medical Service.**—Commissions.
- Ipswich, East Suffolk and Ipswich Hospital.**—H.S. to the Asst. Surgeons, at rate of £144.
- Kettering and District General Hospital.**—Second Res. M.O., £125.
- Kidderminster and District General Hospital.**—Sen. and Jun. H.S.'s, £150 and £100 respectively
- Leicestershire and Rutland Mental Hospital, Narborough.**—Asst. M.O., £350.
- Lincoln City.**—Deputy M.O.H., £600. Also Asst. School M.O., £500.
- Liverpool Royal Children's Hospital, Myrtle-street.**—Res. Cas. O., £250. Res. M.O. and Res. Surg. O. for Heswall Branch, each at rate of £120. Also two Res. H.P.'s and two Res. H.S.'s for City Branch, each at rate of £100.
- Liverpool Sanatorium, Delamere Forest, Frodsham.**—Second Asst. to Med. Supt., £250.
- London County Council.**—Asst. M.O. (Grade I.), £350. H.P., at rate of £120. Also Temp. Dist. M.O., at rate of £125.
- London Hospital, E.**—First Asst. and Reg. to Children's Dept., £300.
- London Lock Hospital, 283, Harrow-road, W.**—Res. M.O., at rate of £175.
- London University.**—Examinerships.
- Maidstone, Kent County Ophthalmic and Aural Hospital.**—H.S., at rate of £200.
- Manchester, Crumpsall Hospital and Institution.**—Res. Asst. M.O., £350.
- Manchester, Hulme Dispensary, Dale-street.**—Res. M.O., £250.
- Manchester Royal Children's Hospital, Pendlebury.**—Res. M.O. and Res. H.S., at rate of £125 and £100 respectively.
- Manchester Royal Infirmary.**—Chief Asst. to Surg. Units, £250.
- Manchester, St. Mary's Hospitals.**—Res. Obstet. O., £175.
- Manor House Hospital, Golders Green, N.W.**—Jun. M.O., £200.
- Marie Curie Hospital, 2, Fitzjohn's-avenue, N.W.**—Res. M.O., £100.
- Oldham, Boundary Park Municipal Hospital.**—Res. Asst. M.O., at rate of £200.
- Oldham Royal Infirmary.**—H.S. to Spec. Depts. Also Cas. O. and H.S. to Fracture Dept., each at rate of £175.
- Oswestry Robert Jones and Agnes Hunt Orthopaedic Hospital.**—Two H.S.'s, each at rate of £200.
- Oxford, Winfield-Morris Orthopaedic Hospital.**—Res. H.S., £100.
- Princess Beatrice Hospital, Earl's Court, S.W.**—Res. M.O., at rate of £150.
- Putney Hospital, Lower Common, S.W.**—Jun. M.O., at rate of £100. Also Asst. Hon. Physician.
- Queen Mary's Hospital for the East End, Stratford, E.**—Radiologist, £350. Two Cas. and Out-patient Officers, each at rate of £150. Also Anaesthetist, £50.
- Royal Air Force Medical Service.**—Commissions.
- Royal Chest Hospital, City-road, E.C.**—Hon. Physician.
- Royal National Orthopaedic Hospital, 234, Great Portland-street, W.**—Hon. Asst. Surgeon.
- St. George's Hospital, S.W.**—Res. Obstet. Asst., £100.
- Sheffield, Jessop Hospital for Women.**—H.S., at rate of £100.
- Southampton, Royal South Hants and Southampton Hospital.**—H.S. to Ear, Nose, and Throat Dept. and Res. Anaesthetist, at rate of £150.
- South Shields Ingham Infirmary.**—Sen. and Jun. H.S., £200 and £150 respectively.
- Stafford, Staffordshire General Infirmary.**—H.P. and Cas. O., at rate of £150.
- Stamford, Rutland and General Infirmary.**—H.S., at rate of £250.
- Stockport Infirmary.**—H.S., £150.
- Sudan Medical Service.**—M.O., £E.720.
- Surrey County Council.**—Deputy County M.O.H., £1150. Also First Asst. Res. Asst. M.O. for Surrey County Sanatorium, £600.
- Torquay Borough.**—Deputy M.O.H., &c., £600.
- Warwick, Warwickshire and Coventry Mental Hospital.**—Deputy Med. Supt., £600.
- West Bromwich, Hallam Hospital.**—H.P., at rate of £200.
- Western Ophthalmic Hospital, Marylebone-road, N.W.**—Jun. Res. H.S., £100.
- West London Hospital, Hammersmith-road, W.**—Hon. Asst. Anaesthetist. Also Pathologist, £750.
- Wigan, Royal Albert Edward Infirmary and Dispensary.**—H.S., at rate of £150.
- Wolverhampton Royal Hospital.**—H.S. and Asst. Res. M.O., each at rate of £100.
- Woolwich and District War Memorial Hospital, Shooter's Hill, S.E.**—Hon. Asst. Physician.
- Worcester Royal Infirmary.**—H.P. and Jun. H.S., £160 and £120 respectively.
- Worksop, Victoria Hospital.**—Jun. Res., at rate of £120.
- York County Hospital.**—Res. Anaesthetist and second H.S., £150.
- The Chief Inspector of Factories announces vacancies for Certifying Factory Surgeons at Buckhaven (Fife) and Pembroke (Pembrokeshire).

## Births, Marriages, and Deaths

### BIRTHS

- DUNNING.**—On June 19th, at Harpenden, Herts, the wife of Dr. J. B. Dunning, of a son.
- EVANS.**—On June 16th, 1936, the wife of Ernest Sandford Evans, M.R.C.S., L.R.C.P., of Chelford, Cheshire, of a son (stillborn).
- LORING.**—On June 16th, at Wilton-place, S.W., the wife of Dr. John Nigel Loring, of a daughter.
- MACDONALD.**—On June 18th, at Highgate, N., the wife of Dr. George Macdonald, of a daughter.
- PIERCY.**—On June 15th, at Welbeck-street, the wife of J. E. Piercy, F.R.C.S. Edin., of a daughter.
- POPE.**—On June 14th, at Beckenham, the wife of Dr. Samuel Pope, of a son.
- WYNNE-EDWARDS.**—On June 15th, at Sheringham, the wife of Dr. E. C. Wynne-Edwards, of a daughter.

### MARRIAGES

- BORLAND-CARR.**—On June 15th, in London, Douglas Morris Borland, M.B., Ch.B. Glasg., to Vida Sara Maxwell Carr, daughter of W. B. Maxwell, J.P., Carlisle.
- HYSLOP-COLLARD.**—On June 20th, at St. Alkelda's Church, Giggleswick, William Anthony Hyslop, M.B., B.S. Lond., to Irene Marie Challenor (Wendy), younger daughter of the late Gordon Neville Collard and Mrs. D. C. Chesterton of Hove.

### DEATHS

- CHALLENGER.**—On June 20th, at Abingdon, Harry Septimus Challenger, M.R.C.S. Eng., aged 72.
- CRUTTWELL.**—On June 17th, Harry Athill Cruttwell, M.D. Brux., L.R.C.P. Edin., late of Bagshot and Harley-street, W.

**MARGATE GENERAL HOSPITAL.**—A contributory scheme associated with this institution has been in existence for eighteen weeks and already nearly 4000 members have been enrolled. It is hoped to obtain a membership of 10,000 which would provide the hospital with a regular and assured annual income of about £5000.

## NOTES, COMMENTS, AND ABSTRACTS

## HEALTH STANDARDS IN INDUSTRY\*

By H. H. BASHFORD, M.D., M.R.C.P. Lond.

CHIEF MEDICAL OFFICER TO THE POST OFFICE

I SHOULD like to make it clear at the outset that, apart from a few visits to large firms of various kinds—generally in search of information about their welfare and medical services, if any—my own experience of industrial medicine has been confined to the Post Office, with which I have now been associated for nearly thirty years. I also fully realise that, in many respects, the Post Office, as an industrial concern, differs very much, both in its general conditions and the recruitment of its personnel, from other large industries. But since, in the last analysis, every industry depends upon—and is necessarily composed of—men and women and boys and girls, there may be something that we can learn from each other.

## The Medical Services of the Post Office

I will begin therefore by explaining something about the Post Office and its medical services, and its particular approach to those problems of health and physical efficiency which are common to us all. Numerically the Post Office is the largest employer of labour in this country. Its staff consists of about 185,000 men and 55,000 women, of whom about 121,000 men and 35,000 women are what are known as established Post Office servants. This means that the great majority enjoy the privileges, when they retire at sixty—or earlier from ill-health—of a non-contributory pension, based on their years of established service and their closing emoluments, and full pay during sick-leave for a period of six months, followed by half-pay for another six months, followed by pay at pension rate so long as the Post Office is advised by its medical branch that there is a reasonable prospect of resumption to render regular and efficient service in the future. The sick-leave privileges begin from establishment, which is preceded by a very thorough medical examination; but the pension privileges are not obtained until after ten years' established service when, however, they become retrospective for that period.

Further, all established Post Office employees under a salary of £230 a year in London and £215 a year in the provinces receive free medical attention, comprising all the services that might reasonably be expected from a general practitioner. These services are provided by some 2600 local Post Office medical officers, distributed over England, Wales, Scotland, and Northern Ireland. They are general practitioners, who hold the Post Office appointment in addition to their private practices, and who are paid on a capitation basis. For example, in such large towns as Birmingham, Manchester, or Glasgow, the centre of the town would be divided between three or four such doctors, each of whom might have from 300 to 500 Post Office employees on his capitation list. The outlying suburbs of such towns, and smaller towns, such as Bedford and St. Albans, would probably have one such medical officer; and in the smaller villages the local doctor might not have more than a dozen Post Office employees under his care.

This medical service is not, of course, compulsory. If they choose to pay for them, Post Office employees can have their own private or panel doctors. But each local Post Office medical officer is responsible for the supervision of such sick absence and indeed of the sick absence of the whole staff of all ranks in the offices to which he is attached. Private

certificates must be countersigned by him, and panel certificates scrutinised, before pay is authorised; and if he is satisfied, after personal examination, that there is no real disability for work or for temporary lighter work, if this is available, he can advise an immediate return to duty. He is also the first instance examiner of all local candidates for ultimate establishment in the Post Office; the local adviser on medical questions to the postmaster, superintending engineer, and district manager of telephones. He keeps an eye on premises from the point of view of sanitation and ventilation; and he furnishes an annual report to the chief medical officer on the health of the staff under his care, the condition of the local post offices, telephone exchanges, and so on, and, as far as he is able, on the general domestic conditions in which the staff live. This service is controlled by a small whole-time headquarters staff in London, consisting of a chief medical officer, a second or deputy chief medical officer, a senior woman medical officer, and four assistant men and four assistant women medical officers, the latter of whom give clinical attention to the large central staffs of men and women in London, amounting to some 24,000.

The chief medical officer acts in a supervisory and consultative capacity to the whole medical service of the Post Office and advises on all general questions which have a medical aspect. Medical reports upon all candidates for the service, in which some abnormality has been recorded, or in which the local Post Office medical officer has advised rejection, are referred to him; and no recommendations for retirement on the grounds of ill-health are proceeded with until, or unless, he has personally seen all the relative medical evidence. He also deals personally with all appeals against medical rejection for established employment or against retirement on the grounds of ill-health. It has also been found advisable to centralise certain other medical procedures. Every case of contact with infectious disease on the part of a Post Office employee is notified to headquarters, and dealt with on the day of receipt, in order to secure uniformity of action throughout the country—the Post Office having abolished the principle of quarantine in most of such cases, with the saving of many thousands of days of enforced absence, and with no greater incidence than the normal of infectious fevers amongst its staff. All cases of pulmonary tuberculosis are also notified to, and dealt with at, headquarters after a certain period of sick absence. Finally, the chief medical officer is responsible for an annual report on the health of the staff, comprising the vital statistics for the year and the average sick rates for the whole and separate classes of the Services, which are further analysed, for comparison purposes, into those of the Post Office staffs in the largest cities, various typical industrial towns, seaside resorts, and so on. In this way an annual picture of the health of the staff and all its numerous constituent groups can be obtained.

## Records and their Value

Such very briefly is the medical organisation of the Post Office, and now I should like to revert again, for a moment, to its industrial aspect, for it is not only the largest but probably the most various employer of labour in this country. Under its permanent heads, the director-general and deputy director-general, it comprises a board consisting of directors of mails, telecommunications, savings, public relations, personnel and establishment, the accountant-general and the engineer-in-chief, and a considerable administrative and clerical staff. It also comprises postmen, the largest single class, half of which is recruited from promoted messenger boys and half from short-service Army and Navy men, sorters, porters, telegraphists, telephonists, engineers, skilled workmen, linesmen, motor transport men,

\* An address to the National Association of Clayworks' Managers, Scarborough, on June 15th.

wireless research experts, storekeepers, repair shop hands, solicitors, and architects; and its smaller unestablished staff includes boys and girls on the way to becoming established, labourers in the engineering department, and an older class of doorkeepers, cleaners, and liftmen, who are generally retired policemen or men from the Services with some sort of long service pension.

But besides all this, it has this, I think, unique feature. It is the only concern of such magnitude, certainly in this country and probably in the world, that has complete and accurate sick records—under actual working conditions—of nearly a quarter of a million men and women from the ages of 16 to 60. In these records—and the medical service of the Post Office dates back to 1855—there are still, I am sure, unworked mines of information both for industry and medicine, although we have been able, perhaps, to contribute a little. Let me give you an illustration or two. Although the incidence of pulmonary tuberculosis in the Post Office compares favourably with the community at large, and is happily diminishing from year to year, yet in so large a service there must necessarily be a good many cases. We have records at headquarters of nearly 3000 such cases, going back now for twenty years, of which we know the exact incidence, subsequent history, and industrial survival rates; and I do not think that there is a comparable body of such figures elsewhere.

Then again we have records of a very large number of cases of gastric and duodenal ulcer, and we have recently published the after-history of 430 such cases, both surgically and medically treated. Over periods of observation, varying from three to twenty years, we have found that, however treated, these cases under actual everyday working conditions incur very much more sick absence than normal people. More than 30 per cent. of them incur more than a month's sick absence from all causes every year; and on an average more than 50 per cent. incur yearly sickness of a fortnight or over. And this is information that could not have been obtained by even the most careful follow-up departments of hospitals or individual surgeons and physicians.

On the other hand our records have helped us to destroy one or two medical bogies. Thirty years ago, for example, no boy whose urine contained albumin was accepted for any service, however otherwise healthy he might seem, and, if he was considered insurable at all, it was only with a heavily loaded premium. Such boys were often forbidden by family or school doctors to play any sort of game and were generally believed to be suffering from the early stages of Bright's disease. But one of my predecessors as chief medical officer, finding a relatively large number of these otherwise healthy seeming boys coming up for examination, came to the common-sense, but then not generally accepted, opinion that they could not all be thus doomed to premature extinction. He accordingly began, very tentatively, to accept them, and when I first came to the Post Office I found a group of thirty, whom I was able to investigate, some of them after ten years' service. I was able to follow them up for another twenty years, and although the condition of albuminuria persisted in a few, they all remained in good health, barring one or two who had suffered from some quite extraneous complaints, and their sick record was no higher, and often indeed lower, than that of the service in general. Further, it was found after examining or investigating a series of 1500 boys at 14, of all sizes and weights, that one in every twenty presented this condition; and in a series of 5000 girls about 16 per cent. Put briefly we have, I think, been able finally to demonstrate—and it is now generally accepted throughout the medical and insurance worlds—that it is a condition of no serious importance at all. It is upon the basis of these and similar particular prolonged large-scale observations that our own physical standards for the acceptance or rejection of new entrants are very largely based.

Another series of observations made possible by these industrial records may also perhaps be mentioned here. Medical notes are kept of all candidates for Post Office employment, and five years ago I was thus enabled to make an interesting and, I think, encouraging series of comparisons. An unselected, consecutive series of 200 London boys of 16, seeking employment from the same sorts of London families and districts, was compared with a similar series of 200 London boys, who were examined twenty-five years previously. The present-day boys were found to weigh, on an average, 16 lb. more, and to be  $1\frac{1}{2}$  inches taller, than those of the previous generation. A similar comparison between unselected, consecutive groups of 200 girls of 16 examined five years ago and twenty-five years before that, showed that the girls of to-day weighed upon an average 10 lb. more, and were 1 inch taller, than the girls of the last generation. And here again was an investigation that could have been made, I think, in no other industry.

It is realised, of course, that the Post Office, with its special conditions of employment, sick pay, and pensions, has perhaps a greater necessity than some industries to maintain such records as I have mentioned. But with the increasing practice in many other industries of establishing some sort of pension scheme—if for no other reason—I feel that the accurate keeping of the sick records of employees must inevitably spread to these; and enough has perhaps been said to illustrate its value from the larger point of view of the general advance of knowledge. But I should have supposed that it might have even a more so-called practical advantage. Most industries are situated and housed in a particular way, and are dependent upon certain particular technical processes; and from time to time such situations, accommodation, and technical processes are presumably altered. Surely a continuous and accurate sick record of the all-important human personnel, when associated and compared with such changes, should afford information to industrial employers, even in a small business or factory, that must, in some way or other, be ultimately valuable both to them and their workers.

#### Some Problems of Sickness

Turning now to the comparison between sick rates in the Post Office and sick rates in other industries, I must again make an apology because this is doubtless of much more interest to me than to you. But a few general considerations that have emerged from it may, perhaps, at least be suggestive. I have already indicated two difficulties with which such a comparison has been confronted. Very few industries, though their number is increasing, do in fact appear to keep sick records at all, and fewer still seem to have records, covering any substantial number of years, of their retirement rates due to ill-health, and the average age of the employees so retired—figures without which mere sick rates are largely valueless.

Again the Post Office as a whole is not strictly comparable with any other single industry; and it is even difficult to find fair standards of comparison for many of its component groups. But I have been able, thanks to the courtesy of their directors or medical advisers, to obtain figures of sick absence, though not of wastage from ill-health, from some undertakings that pay—or contribute to the payment of—their employees during illness, and also from some that do not. And it must be admitted that their sick rates, especially in the latter group, are usually considerably lower than our own.

Indeed, it has been a common criticism in discussing this question with outside employers of labour, and even with some of our own local medical advisers, that the Post Office cannot expect to have really satisfactory sick rates—whatever that may mean—as long as its employees receive full pay when they are absent for illness. Well, I think, superficially speaking, that there is something in such a criticism, though not very much. There are undoubtedly

some men and women who may take advantage of such a system. But my experience has been that there are relatively not very many. And medically speaking, I think there will be general agreement that it is definitely undesirable for a man or woman, directly he or she becomes ill, to incur the additional anxiety of an immediate financial loss.

Moreover there is another side to the picture. Although the loss of wages or salary may be an incentive to an early return to duty, there are not a few instances, of which there is plenty of evidence, of men and women, especially perhaps the younger, coming back to work much too soon, simply because they cannot afford to remain away until they are properly fit. This may well lead to another illness, when the same process is repeated, and ultimately perhaps to a more or less prolonged breakdown, whereupon their firm or industry says good-bye to them. And a quiet talk with the almoners of some of our larger hospitals, who are then faced with the problem of these people, would reveal a somewhat seamier side of this particular way of treating sick absence.

Speaking for the Post Office, at any rate, I should regard any move in the direction of an immediate curtailment of pay during sick absence as a retrograde step from every point of view; and I am sure that, from such a long-distance standpoint of regarding health as we in the Post Office must necessarily take, a low sick rate purchased at such a price—to put it on the lowest possible grounds—would be the worst sort of economy.

Granted this, however, and human nature being what it is, some form of expert and understanding supervision of sick absence does, I think, become necessary, and not always in the interest alone of the employer or paymaster. I have said that, for the great majority of its employees, the Post Office is a whole-life, pensionable service. But it is ten years before any of its employees reach what we call pensionable status; and if, during these early years of service, we find some young man or woman incurring repeated or heavy sick absences for minor or more serious illnesses, we are sometimes obliged to retire them before they become a permanent charge upon the State.

Here again is illustrated the value of an accurate routine sick record. It enables supervising officers to pick up such a case and refer the boy or girl, or young man or woman, to the appropriate local medical adviser; and we often find, in cases of repeated minor sick absence, that the employee in question has no idea of the amount of sick absence incurred. Some of it may be due to thoughtlessness, or what we may call "gutlessness," or a light-hearted taking of sick leave for not quite necessary reasons; and a quiet talk often has the effect of an immediate and permanent improvement. It may also perhaps reveal some minor defect, such as septic tonsils or carious teeth, attention to which again results in an immediate and permanent improvement.

But if, in spite of all this, the heavy sick record persists, retirement may become advisable on medical grounds, and not necessarily, as I have said, with wholly tragic results to the employee. It may be, and often is the case, that he or she is really a square peg in a round hole, and that the sick absence is a reflection of this. In such cases, retirement may well be the stimulus to find some more congenial sphere of action.

At the other end of the scale there is the group of middle-aged or elderly men and women who are beginning to require repeated and lengthy sick absences for such conditions as chronic rheumatism or bronchitis. Here again—and accurate sick records can only show this—there comes a time when retirement is probably in their own truest interests as well as in those of their employers. The fact that they can so retire on a pension must, of course, be an immense help and satisfaction to all concerned.

I need not stress the obvious advantages of proper and expert sick-supervision from the points of view of

detecting and perhaps preventing serious illness; of discovering men and women who are medically affected by certain industrial processes and not by others; or by certain types or hours of duties and not by others. And I would suggest that this is much more easily discovered by medical advisers, whether whole time or part time, who are equally familiar with the particular works and processes involved, the human personnel employed, and their year to year medical records—his knowledge being amplified, perhaps, by that of the private or panel medical attendant, who may be more familiar with domestic strains and stresses unknown at the factory, works, or office.

#### Physical Standards for Entry

So much for the keeping of sick records and the supervision of sick absence; and the question of the physical standards required at the beginning of employment must vary very widely with different industries and individual conditions of pay and pensions. In such a service as the Post Office, with its sick pay privileges and eventual pension rights, admission to its established ranks would necessarily be somewhat stricter than in industries that do not undertake such obligations. An actuarial or group-expectation standard must be applied rather more stringently in the first case than in the second. For example, a boy or girl with a well-compensated organic lesion of the heart may be perfectly competent—time alone can show—to perform any ordinary task for any ordinary lifetime. For a permanent pensionable service they might nevertheless be an unjustifiable risk; and the same would apply to cases of cured or arrested tuberculosis and sundry other conditions.

Standards of vision again must vary from employment to employment. Colour-blindness may disqualify for some and not for others; and this applies, of course, to a very large number of other conditions. Boys who are to become postmen, for instance, in the Post Office, must be free from weaknesses of the legs and feet that would not disqualify them for clerical or certain technical employments. I do think, however, that employers would render a great service, both to themselves and the community, if they insisted on healthy mouths and throats, before accepting young people for permanent employment. But it seems to me that this question of physical standards at entrance can only be satisfactorily settled by each industry in the light of its own requirements; and once more this can only be scientifically determined—or so it seems to me—by the records of its own sick absences and retirements from ill-health, and their causes, carefully kept by the industry concerned, and reviewed in the light of its accumulated experience over a number of years.

#### The General Health and its Maintenance

With regard to the general health of any body of employees, I have said enough, perhaps, to indicate that—important as they must always be as a rough index—sick rates are not necessarily a complete index of health. A low sick rate, under certain conditions of easy dismissal and a disregard of human labour wastage, may well be compatible with a far from desirable general standard of health. Given conditions, however, of reasonable security of tenure, of reasonable hopes of promotion, and of reasonable pay during illness, they do remain the best indication of the general health—and, incidentally, happiness and probable efficiency—of any large staff. And to lower sick rates, and keep them as low as possible, must or should be the concern of every enlightened employer or board of directors. Adequately chosen and examined entrants and adequate medical supervision during employment can help in attaining this. And here I should like to say a word in favour of what we know in the Post Office as the single-day letter privilege. This gives the right to all employees to be away for a day for health reasons on their own letter of explanation. A maximum of seven such

days in the year is allowed but is very seldom reached; and in practice it has been found, in a very large staff, that the average use of this letter is less than one per man per year.

It may be argued that such a privilege is open to abuse, and there may be a few employees who from time to time do abuse it. But it has been our experience that the abuse of it is very rare, and since—in our case at any rate—such single days are of course noted in the sick record, cases of possible abuse can easily be investigated. Taken all round, it may be said that this privilege implies the recognition that men and women are not machines and that they all may occasionally have an "off" day, when a few hours' rest or change may restore physical and mental horizons. Moreover, in employees subject to such complaints as migraine or asthma, such a day taken at discretion may well save several under medical certificate. Looking at it all round, I feel that this privilege, reasonably supervised, is one that is likely, on balance, to reduce sick absence and contribute to the health of employees.

Again, I need not dwell probably upon the value of such ancillary agencies to health as sports clubs of various kinds, which also afford the very salutary and humanising opportunity of allowing the chairman to be beaten by the office boy at tennis or golf. And finally, from what I have been able to see of modern factory and industrial designing and planning, I need not perhaps emphasise the effect of adequate lighting and a cheerful and welcoming scheme of colour decoration in working and retiring rooms. These should be adapted to the position of the rooms, a warmer scheme of colouring for those facing north or east, a cooler for those facing south or west, a warmer scheme for sedentary, a cooler for manual workers. And although the ultimate effect of these on sick rates may be difficult to assess or prove by figures, I am convinced that they must tend in the direction of lowering sick rates.

Much could also be said, of course, upon the influence of atmosphere—in a psychological sense—upon health as well as sick rates. One would suspect, for instance, in an industry, works or factory, where the chief emphasis was upon output, and where supervisors were selected and educated to regard this primarily if not alone, that the standard of health might well leave a good deal to be desired—and probably, in the long run, the quantity and quality of the output also. On the other hand, in an industry whose supervisors, both men and women, were selected, apart from technical qualifications, by virtue of their general knowledge of, and sympathy with, their fellow-beings—and above all by virtue of their ability to be blind at the right moment—one would expect both the health standard and, I should guess, even the output to be relatively higher. In other words, the happy ship is generally, I think, the healthy and efficient one.

## INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED  
JUNE 13TH, 1936

**Notifications.**—The following cases of infectious disease were notified during the week: Small-pox, 0; scarlet fever, 1674; diphtheria, 853; enteric fever, 31; pneumonia (primary or influenzal), 737; puerperal fever, 38; puerperal pyrexia, 114; cerebro-spinal fever, 12; acute poliomyelitis, 7; acute polio-encephalitis, 2; encephalitis lethargica, 8; relapsing fever, 1 (Bolton); continued fever, 1 (Paddington); dysentery, 12; ophthalmia neonatorum, 114. No case of cholera, plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the London County Council on June 19th was 4456, which included: Scarlet fever, 1040; diphtheria, 686; measles, 1508; whooping-cough, 531; puerperal fever, 12 mothers (plus 7 babies); encephalitis lethargica, 284; poliomyelitis, 1. At St. Margaret's Hospital there were 28 babies (plus 16 mothers) with ophthalmia neonatorum.

**Deaths.**—In 122 great towns, including London, there was no death from small-pox, 2 (0) from enteric fever, 38 (13) from measles, 4 (0) from scarlet fever, 32 (7) from whooping-cough, 18 (2) from diphtheria, 44 (23) from diarrhoea and enteritis under two years, and 24 (4) from influenza. The figures in parentheses are those for London itself.

Hull reported 5 deaths from measles, no other great town more than 2. Sheffield had 6 deaths from whooping-cough, Birmingham 3. Deaths from diphtheria were reported from 14 great towns, 4 from Liverpool. Portsmouth and Grimsby each had one death from enteric fever.

The number of stillbirths notified during the week was 270 (corresponding to a rate of 36 per thousand total births), including 41 in London.

## Medical Diary

*Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.*

### SOCIETIES

- ROYAL MEDICO-PSYCHOLOGICAL ASSOCIATION.  
WEDNESDAY, July 1st, THURSDAY, and FRIDAY.—Annual Meeting at Folkestone.

Abdelsamie, L., early amputation for injury, 187, (A) 1249  
Abdomen—Early Diagnosis of Acute Abdomen (Z. Cope) (R) 149; omental dermoid (E. N. MacDermott) 898; varicosities of (A. L. d'Abreu) 84, (J. W. Riddoch) (C) 227; see also Hemorrhage and Peritoncum  
Abel, A. L., intravenous anaesthesia, 422, 600  
Aberdeen University Club, London, 694  
Abortion—alleged criminal, inquest depositions and (ML) 278; habitual (A) 728; law of (LA) 1073, 1388; maternal mortality and, 404, (PI) 814; Roman Catholicism and, 640, (E. E. Ware) (C) 741  
Abrahams, A., on fatigue, 662, (C) 742  
Abyssinia—British Red Cross units, 59, 158, (A) 441, Italian bombing and (PI) 402, 455, 552, (PI) 635, 694, (PI) 696; Italian arrest of British subject (PI) 1269  
Academic Assistance Council (Lord Rutherford) (C) 739, (LA) 727  
Accidents, see Industrial medicine, Negligence, and Road accidents  
Acetic acid poisoning (PI) 814  
Acetonuria, see Glycosuria  
Acetylcholine—and derivatives (LA) 903; for paroxysmal tachycardia (A. B. Stenhouse) (C) 391; see also Myasthenia gravis and Tissue extracts  
Acholuria jaundice, see Jaundice  
Acriflavine—as urinary antiseptic (E. W. Assinder) 304; uses of, 293  
Actinotherapy—congress of, 233; Jesionek, A., work of (A) 440  
Adams, A., on bronchial carcinoma, 201  
Addison's disease—blood in (E. N. Allott) 1406; potassium-sodium ratio in (LA) 1304; see also Sodium chloride  
Adelphi, The, demolition of (LA) 905  
Adler, A., on psychological approach, 1117  
Adler, S., relapsing fever (C) 448  
Adolescence—education and, 274; psychological disturbances in (R. D. Gillespie and R. A. Q. Lay) (P) 1129; Youth, Sex, and Life (G. M. Cox) (R) 1302; see also Puberty  
Advertising, see Drugs  
Africa—medical service in West Africa (PI) 1093; vanishing fauna of, 1096  
Agranulocytosis—amidopyrin and (ML) 54; meningitis and (S. H. Epstein) (C) 116  
Air, see Ventilation  
Air attacks—food contamination and (PI) 1040; protection against (PI) 514, 580, (PI) 634, 757, (PI) 814, 873, (PI) 924, 978, (PI) 1215, 1501, medical practitioners and (PI) 1501; see also Abyssinia  
Air embolism, pleural shock and (C. O. S. B. Brooke) (C) 56  
Air transport—licence renewals, venereal disease and (H. W. Bayly) (C) 1329; medical examination of pilots (PI) 634; nervous disorder and (A) 1485; oedema of ankles and (M. Weinbren) (C) 170  
Aird, I., on intestinal strangulation 601  
Aitken, A. B., death of, 124  
Aitken, R., on lupus vulgaris, 388  
Albuminuria, see Pregnancy  
Albury, J. B., appointment, 289  
Alcock, N. S., lymphocytic meningitis, 650, (LA) 670  
Alcohol—in hospital practice (A) 617; injections of, 41, 80, (A) 99, 595, (A) 852, 730  
Alcoholism—acute, 50; dangers of, instruction in (PI) 749; manic-depressive insanity and (W. N. East) 161, (A) 155; pseudo-paresis and (E. W. Anderson) 477; see also Road accidents  
Aldridge, H. R., and Hartley, Sir P. H.-S., Johannes de Mirfield of St. Bartholomew's, Smithfield (A) 1079  
Aldridge-Blake scholarship, 172  
Alexander, F. W., sodium mandelate in chronic cystitis (C) 391  
Allen, C., epilepsy and allergy (C) 805  
Allen, Lord, on psychology of international relations, 274  
Allergy—Alleged Dye Dermatitis Committee (W. J. O'Donovan) (C) 1329; asthma and epilepsy (K. Costello and J. T. Fox) 660, (G. H. Oriol) (C) 741, (C. Allen) (C) 805; focal infection and (LA) 1480; food and drug, 754; hay-fever (P. Franklin) (C) 1442, (A) 1424; neuropathic eczema, 1300; pathergy and (S. Leites) 1348, (A) 1364; phlycten and (A) 909; Pollen Grains (R. P. Wodehouse) (R) 1118, (A) 1126; uteraria (A) 618; vulval and anal pruritus and (E. Hunt) 592  
Allison, P. R., brain and lung abscesses in otitis media, spontaneous pneumothorax and, 1060  
Allott, E. N., blood in Addison's disease, 1406; on salt in Addison's disease, 604  
Almoners—Cummins, A., work of (A) 442; Hospital Almoner, 64; Medical Social Work (H. M. Bartlett) 875  
Alstead, S., effect of chloral hydrate on heart, 938  
Altschüler, E., tuberculous thrombophlebitis, 948  
Aluminium—cooking vessels (R. M. Le II. Cooper) (C) 118; splints (A. P. Bertwistle) 146  
Alvarez, W. C., gastric acidity (C) 740  
Ambulances—air, in Britain, 1042; hospitals and (PI) 514; local authorities and (PI) 456  
Amenorrhoea—ovarian and endometrial graft for, 666; ovarian extraversion for, 315  
American Academy of Arts and Sciences, 447  
American Medical Association—ergot alkaloid (A) 909; meeting, 1432  
Amidopyrin—agranulocytosis and (ML) 54; scheduled as a poison (PI) 456  
Ammonium chloride, see Edelema  
Ammonium mandelate, see Urinary Infections  
Amoebic dysentery, see Dysentery  
Amputation, early, for crushed limbs (L. Abdelsamie) 187, (A) 1249, (L. Stiven) (C) 1411  
Amyl nitrite (A) 270  
Anemia—acute febrile, dental sepsis and (P. C. Gibson) 994, (C) 1143, (F. P. Weber) (C) 1086, (LA) 1479; focal infection and (W. P. Murphy) 1451; iron in (L. J. Witts) 1, (A) 493; megalocytic, in British Guiana (A) 1421; pregnancy and (J. A. Boycott) 1165; remedies for, tests of (A) 493; see also—  
Anemia, pernicious—Castle's intrinsic factor in (C. C. Ungley and R. Moffett) 1232, steatorrhoas and, 1298; experimental (A) 493, liver extracts and (A) 98; focal infection and (W. P. Murphy) 1451; purified liver fraction in (C. C. Ungley, L. S. P. Davidson, and E. J. Wayne) 349, (C) 448, (J. F. Wilkinson) 354, (A) 380, 622; spectrographic anomalies of gastric juice in (L. Karczag) 947; stomach and (A) 154; syphilis and (C. R. Box and A. M. Gill) 24, (R. Miller) (C) 115; see also Stomach  
Anaerobic septicæmia (A. Lemierre) 701  
Anæsthesia—basal narcosis (A) 906, coramine and (A) 1420; choice of, 89, 125; deaths from (A) 438, (PI) 456, cerebral surgery and (Z. Mennell) (C) 504; dental prop (W. W. Mushin) 1062; in thoracic surgery (A) 383; intravenous (R. Jarman and A. L. Abel) 422, 690, (S. Horsley) (C) 690; non-volatile narcotics (A) 557; shock and (A) 36; see also Avertin, Cyclopropane, Ether, Midwifery, and Paraldehyde  
Anæsthesia, spinal—pantocain (A. A. Nabi) 779; risks of (A) 616  
Anæhemim, see Anæmia, pernicious  
Anal, see Anus  
Analgesia, see Anæsthesia and Pain  
Anatomy—clinical, of the arm (Praktische Anatomie) (T. von Lanz and W. Wachsmuth) (R) 29; Companion to Manuals of Practical Anatomy (E. B. Jamieson) (R) 91; see also Biology  
Anderson, E. W., alcoholic pseudo-paresis, 477  
Anderson, G. C., badges for doctors' cars (C) 1329  
Andrewes, C. H., on influenza (LA) 32; on viruses of rabbit tumours (A) 1125  
Aneurysm—of splenic artery (S. E. Osborne) 1007; ruptured, of gastric artery (E. E. Lewis) 255; sciatica and, 875  
Angina pectoris—amyl nitrite in (A) 270; pain of, relief of (A) 157; see also Heart and Heart disease  
Animals—diseases of, research on (PI) 458; narcosis in (A) 557; poisons for rodents, 404, 580; University of London Animal Welfare Society, 638; see also Biology and Vivisection  
Ankle—oedema of, air transport and (M. Weinbren) (C) 170; sprained, novocain injection for, 1431  
Ankylostomiasis in Indian seamen (A. H. Walters, G. C. Low, and P. H. Manson-Bahr) 599  
Ansari, M. A. (O) 1212  
Anschutz, W., resection in cancer of stomach, 1175, (LA) 1190  
Antenatal, see Childbirth  
Antivivisection, see Vivisection  
Anus—fistula-in-ano (J. P. Lockhart-Mummery) 657; gonorrhœa of (A) 962; wounds of (W. B. Gabriel) 1345; see also Pruritus  
Anwyl-Davies, T., Treatment of Venereal Disease in General Practice (R) 1357

Appendicitis—260; in infant (F. H. Coleman) 1008  
 Appendix, torsion of, in pregnancy (G. Flatley) 1357  
 Apperley, F. L., gastric acidity, significance of, 5, (A) 35, (C) 630  
 Appointments, weekly lists of, 59, 122, 174, 233, 289, 310, 405, 462, 516, 582, 642, 700, 753, 817, 874, 930, 986, 1042, 1100, 1156, 1219, 1273, 1330, 1390, 1449, 1503  
 Arch, A. J. (O) 509  
 Archer, H. E., excretion of ascorbic acid, 710, (A) 729  
 Arm, see Limbs  
 Army—cerebro-spinal fever in (PI) 750; health of, 220; recruits, defective health of (PI) 577, 696, 1269, 1415; see also Royal Air Force and Services  
 Arnott, W. M., on experimental hypertension (A) 380  
 Arteries—athero-sclerosis, thyroid gland and (N. P. Dungal) 1354; Diseases of Peripheral Arteries (S. S. Samuels) (R) 1012, (C) 1382; embolotomy (LA) 33, (H. I. Deitch) 475; obliterative disease of, 120, 209, 540, (A) 674, 1384, intermittent claudication and (H. T. Simmons) 73; pulmonary embolism, Trendelenburg operation for (A) 1365; see also Hemiplegia and Tissue extracts  
 Arthralgia, bismuth injections and, 65  
 Arthritis, see Rheumatism  
 Artificial pneumothorax—in pleurisy and pneumonia (A. R. Majumder) (C) 226; see also Tuberculosis, pulmonary, surgery of  
 Artificial respiration—for three and a half years (P. M. T. Kerridge) (C) 504; in nicotine poisoning (LA) 555; see also Inhalation therapy  
 Aschheim-Zondek reaction—in teratoma testis, 315; litigation and, 1136  
 Aschoff, L., seventieth birthday of (A) 100  
 Ascorbic acid, see Scurvy  
 Ashworth, J. H., death of, 389  
 Asphyxia neonatorum, nitrous oxide and (A) 1249  
 Aspleny, W. W. R. (O) 1212  
 Assinder, E. W., acridavine as urinary antiseptic, 304  
 Association for Moral and Social Hygiene, 873, (A. Neilans) (C) 923  
 Astbury, W. T., on X ray analysis of proteins, 1152  
 Asthma—epilepsy and (K. Costello and J. T. Fox) 660, (G. H. Oriol) (C) 741, (C. Allen) (C) 805; nervous disorder and (A) 96, 208, (S. Ingvær) 313, 805; prognosis in (L. J. Witts) (P) 273; Treatment of Asthma (F. T. Harrington) (R) 786  
 Atabrin poisoning (M. V. Govindaswamy) (C) 56  
 Athero-sclerosis, thyroid gland and (N. P. Dungal) 1354  
 Athletics—endurance and (LA) 1074; fatigue and, 662, (A. Abrahams) (C) 742; hygiene of, 1153; see also Physical education  
 Atkins, H. J. B., circumcision forceps (NI) 610  
 Atlanto-axial joint, subluxation of (J. T. Chesterman) 539  
 Atmospheric pollution—coal fires and (PI) 696; exhibition, 816; fog, basis of (A) 1077; report on (A) 561; smokeless fuel and (PI) 577  
 Atophan in rheumatism, fatality following (ML) 1379  
 Atropine, large doses of (A) 908, 986  
 Audy, J. R., foreign body in heart at birth (C) 418  
 AUSTRALASIA, CORRESPONDENCE FROM.—  
 Intravenous olive oil emulsion therapy, 860—Maternal and infant welfare, 861—Motor accidents, 861—Post-graduate work, 501  
 Australasian College of Physicians (A) 1251  
 Australian and New Zealand Association for the Advancement of Science, 1272  
 Autopsies, see Post-mortems  
 Avartin in childhood (A) 209  
 Ayad, H., hypervitaminosis D (C) 972

## B

Bachmann, E., on after-care of tuberculosis, 558  
 B. *aertryckii* food poisoning (E. R. Jones and H. D. Wright) 22  
 B. *asiaticus*, diarrhoea and (G. Slot and D. Blomfield) 1116

B. coli, see Urinary infections  
 Backache, low, 1200

Urology—Cystoscopy and Urography (J. B. Macalpine) (R) 1360; text-book of (Traité d'urologie) (G. Marion) (R) 846; Urology in Women (E. C. Lewis) (R) 552; Year Book of Urology (J. H. Cunningham) (R) 608

Urticaria (A) 618

Uterus—bleeding from, treatment of, 914, 916; conservative treatment of, 863, (LA) 1191; endocervicitis, 865; endometrial graft, 666; expulsive force of (C. Moir) 414; hysterectomy forceps (W. M. H. McCullagh) (NI) 841; hysteroscopy (A) 791; myomectomy, 863; rupture of (I. H. K. Stevens) 538, placenta previa and, 952; tuberculosis of, 1241; see also Cancer of, Genito-urinary, and Vaginal

## V

Vacancies, weekly lists of, 59, 124, 178, 234, 294, 342, 408, 462, 520, 582, 642, 700, 758, 818, 874, 930, 980, 1045, 1099, 1155, 1222, 1273, 1332, 1386, 1448, 1504

Vaccination—deaths following (PI) 513, 576; encephalitis and (PI) 456, (A) 1022; lymph supplies for (PI) 513; see also Small-pox

Vaginal—discharge, devesgan in (A) 382, (S. G. Luker) (C) 508, (K. Duff) (C) 571, (J. Marshall) (C) 630, (R. Kuhn) (C) 691; discharge, pruritus and (A. Savill) (C) 691; fistula (G. S. Woodman) 1112; see also Genito-urinary

Valentine, F. C. O., staphylococcal toxin, 526

Van den Berg, M. R. H., on dispensary organisation, 856

Van den Bergh reaction, 1475

Van de Velde, Th., Ideal Birth (R) 955

Vann, A. M. (O) 920

Variations, see Evolution

Varicose veins, see Veins

Variola, see Small-pox

Varrier-Jones, Sir P., on after-care of tuberculosis, 857

Vasomotor responses (A) 326; see also Tissue extracts

Vasotomy, outfit for (J. F. Peart) (NI) 488

Vasovagal attack (T. E. Gumpert) 85, (T. W. Preston) (C) 170

Veins—phlebitis, 606, (H. I. Biegeleisen) 944, (C) 1499, (R. T. Payne) (C) 1034, (M. De Lacey) (C) 1086, tuberculous (E. Altschüler) 948; varicose, injection treatment of (M. J. Bennett-Jones) 537, (C) 1086, (S. McAusland) (C) 1034, thrombosis of vena cava and (A. L. d'Abreu) 84, (J. W. Riddoch) (C) 227; see also Claudication

Veneral disease—Air Ministry and (H. W. Bayly) (C) 1329; in France, 50, 970; in Hungary, 801, 1431; in seamen (A) 1193; Treatment of Venereal Disease in General Practice (T. Anwyll-Davies) (R) 1357; Venereal Disease Act infringement (ML) 800; word "venereal" (A) 438; see also Gonorrhœa, Prostitution, and Syphilis

Ventilation—air-conditioning (LA) 848; temperature and humidity in hospitals and schools (PI) 749

Verity, G., death of, 556

Vernon, E. M. (O) 452

Vertigo—aural, operation for (A) 1366; injury and, 660

Vesicovaginal fistula (G. S. Woodman) 1112

VIENNA, CORRESPONDENCE FROM.—Bucura, C., death of, 109—Busson, B., death of, 388—Coronary occlusion, 388—Dohan, N., death of, 109—Electropathology museum, 801—First-aid society, 388—Insurance, health, 1204—Maresch, Prof., death of, 388—Micro-chemistry, society for, 1205—Passim, F., death of, 109—Practitioners, age-groups of, 109—Psittacosis, 801—Tuberculosis, 109

Violinist, armless (The Armless Fiddler) (C. H. Unthan) 237

Viper venom, see Russell viper venom

Viruses—cancer (Sir R. Muir) 877; fibroma and myxoma, in rabbits (A) 1125; influenza (LA) 32, common cold and (LA) 1479; lymphocytic meningitis (G. M. Findlay, N. S. Alcock, and R. O. Stern) 650, (LA) 670; Plant Viruses (K. M. Smith) (R) 1013; research on, 1434; Rift Valley fever (R. D. MacKenzie and G. M. Findlay) 140; trachoma (A. F. MacCallan) 215; tumour-producing, tar and (A) 1420

Viscera, transposition of (E. A. Cockayne) (C) 1442

Visscher, M. B., and Smith, P. W., Experimental Physiology (R) 317

Vital statistics—birth-rate in France, 278; birth-rate, mother's age and (PI) 1094; for 1935 (A) 210; infant mortality in Rumania, 626; in Scotland, 918; life table, 636, (A) 674; mortality from phthisis in young adults, 219; mortality, trends of, in United States, 917; population trends (A) 210, 674, 791, in India (A) 39; Poverty and Health (G. C. M. M'Gonigle and J. Kirby) (R) 1358; see also Maternal mortality

Vitamin A—deficiency, P-P factor and (J. V. Landor) (C) 1441; deficiency, tests for (L. J. Harris) 966, (A) 964

Vitamin B—deficiency, biochemical lesion in (R. A. Peters) 1161, (B. H. Shaw) (C) 1265; excretion of, in urine (L. J. Harris and P. C. Leong) 886, 967, (A) 964; P-P factor, deficiency of (J. V. Landor) (C) 1441; injection of, in nervous diseases (A) 727, (W. N. Leak) (C) 867, (W. R. Russell) (C) 922; in neuritis of pregnancy (G. W. Theobald) 834; in standard diets, 605

Vitamin C, see Scurvy

Vitamin D—hypervitaminosis, cod-liver oil and (L. Thatcher) 20, (A) 36, (R. T. Hewlett) (C) 115, (H. Ayad) (C) 972; unexpected rickets and (A) 36

Vitamin E—abortion and (A) 728

Vitamins—deficiency of, tests for (L. J. Harris) 966, (A) 964; immunity and (A) 852; research on, 1436; tissue culture and (A) 1424; Vitamins in Theory and Practice (L. J. Harris) (R) 609; see also Diet and Nutrition

Vivisection—charitable bequests and (ML) 624, (Sir L. Rogers) (C) 805; Research Defence Society and (A) 1309

Volkmann's ischæmic contracture (A) 1421

Von Lanz, T., and Wachsmuth, W., Praktische Anatomie (R) 29

Von Weizsäcker, on work and disease, 857, (A) 906

Vulva, see Pruritus

## W

Wachsmuth, W., and von Lanz, T., Praktische Anatomie (R) 29

Wakeley, C. P. G., prophylactic enucleation of lower wisdom tooth follicles (C) 1036

Wales—bronchitis and tuberculosis in (PI) 1325; Penmaenmawr, climate of, 237; tuberculosis in (PI) 576; see also Silicosis

Walker, A., on induction of labour, 1176
